ARTICLES

Twin Hatchlings Of *Trimeresurus flavoviridis* (Viperidae)

Although some instances of twinning in reptiles have been reported (Bellairs 1981; Carpenter and Yoshida 1967; Shuette 1978; Singh and Thapliyal 1973; Tryon 1980), few of these accounts have been of normal twin hatchlings (Curtis 1950; Fukada 1978). Here, we describe twin hatchlings and their clutch-mates in *Trimeresurus flavoviridis*, in comparison with eggs and hatchlings of this species in the Okinawa Islands.

A female *T. flavoviridis* (SVL = 1080 mm, mass = 507.6 g) was collected in Itoman City, southern Okinawa Island on 11 June 1988. The specimen had the yellow ground color typical for this species. On 25 July 1988, the snake laid seven eggs and decreased its body weight to 322.0 g. Each egg was incubated in a separate container with wet cotton substrate at fluctuating temperature (range 21.8-30.8 °C).

The eggs measured 47-60 mm in length, 25-27 mm in width, and 22.9-28.8 g in mass. All eggs were of normal size compared with means (N, SD, range) for eggs (all measured within one day after oviposition) of *T. flavoviridis* in the Okinawa Islands: 56.0 mm (676, 7.8, 40-83) in length, 28.5 mm (676, 2.4, 22.5-36.0) in width, and 27.2 g (694, 5.3, 17.9-45.3) in weight.

Twins hatched from the longest, most slender, and heaviest egg in the clutch. The egg containing twins hatched on 4 September 1988, with the remaining six eggs hatching on 5-6 September. All eight hatchlings appeared normal in morphology and behavior. The twins had normal yellow ground color, with minor head pattern differences between the two (Fig. 1). Three of their hatchmates had a rare white ground color. Five hatchlings, including the twins, were sacrificed within one day of hatching.

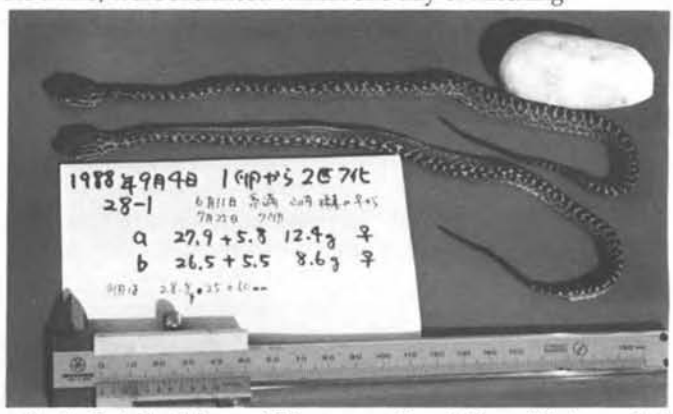

Fig. 1. Twin hatchlings of *Trimeresurus flavoviridis* and their egg shell.

TABLE 1. Measurements of eggs and hatchlings, including twins, of *Trimeresurus flavoviridis* from Itoman City, southern Okinawa Island. All measurements taken within one day following oviposition or hatching. WI = without internal organs; PB = proportions (%) / WI.

Egg No.	Egg weight	SVL	Tail length	Body weight		Yolk Body		Fat Body		Liver	
				Whole	WI	Weight	PB	Weight	PB	Weight	PB
	(g)	(mm)	(mm)	(g)		(g)		(g)		(g)	
1	28.8	279	58	12.4	7.21	2.67	37.0	0.61	8.46	0.34	4.72
1	28.8	265	55	8.6	6.18	0.32	5.2	0.49	7.93	0.26	4.21
Total				21.0	13.39	2.99	22.3	1.10	8.22	0.60	4.48
2	25.1	330	74	19.8	12.90	2.22	17.2	1.12	8.68	0.64	4.96
3	22.9	311	69	17.5	11.12	2.06	18.5	1.03	9.26	0.74	6.65
4	23.9	318	72	18.4	11.33	2.49	22.0	1.04	9.18	0.61	5.38
5	25.7	334	76	19.3							
6	25.1	330	66	18.9							
7	25.1	321	64	18.5							

Both twins were female and had the same number of body scale rows (33), and subcaudals (80), with seven subcaudals at the tail tip not separated in the larger twin. Ventral counts of the larger and the smaller twins were 229 and 226 (plus two small plates), respectively. These scale counts were within the ranges for this species (Koba 1962; Takara 1962).

The smaller twin (265 mm SVL, 8.6 g) was the smallest hatchling *T. flavoviridis* we have recorded in the Okinawa Islands (mean, N, SD, range of SVL and body weight: 331 mm, 315, 25, 265-403; 18.2 g, 314, 3.7, 8.6-31.5, respectively, inclusive of this clutch) and is smaller than others reported previously (see Kamura 1975; Koba et al. 1967; Takara 1962). Total body weight of the twins (21.0 g) was similar to the expected weight for a single normal hatchling (19.5 g), calculated from regressions between egg weight and hatchling weight of this species in the Okinawa Islands (Nishimura, unpublished). Weight proportions of fat body and liver to body weight without internal organs (WI) were similar among the twins, hatch-mates, and hatchlings in the Okinawa Islands (mean, N, SD = 9.45%, 29, 1.61; 5.61%, 29, 0.91, respectively) (Table 1). The larger twin had more yolk for its size than the smaller twin, and the proportion of the total weight of yolk body to the total WI of the twins was standard for a single hatchling of this species (mean = 18.5%, N = 26, SD = 10.4).

Other reports of twins in oviparous colubrids agree with our findings that this anomaly has been associated with the longest egg (Fukada 1978; Singh and Thapliyal 1973) and the earliest hatching within a clutch (Fukada 1978). These tendencies may be related to the fact that the longest (and most slender) eggs tend to be formed at the anterior or posterior end of the abdominal cavity in *T. flavoviridis* (Nishimura, pers. observ.).

Acknowledgments.—We wish to thank A. Mori and H. Ota for providing literature.

The "New" Herpetofauna of Guam, Mariana Islands

The movement and establishment of non-indigenous fauna and flora throughout the Pacific Basin are well recognized (Drake et al. 1989). Non-native plants, insects, terrestrial molluscs, freshwater fishes, and terrestrial vertebrates have become established on many islands, potentially causing substantial perturbations in ecosystems.

Since World War II, Guam (a territory of the United States and the southernmost major island in the Mariana archipelago) has enjoyed an enormous economic boom and is now a major shipping and air travel hub for the western Pacific. Because of this status, substantial amounts of cargo, goods, and people from the Pacific Basin and Rim pass through Guam. This increased movement of materials has been reflected in the number of extralimital species of amphibians and reptiles (15) that have been recorded on Guam since World War II and underscores the apparent ease with which non-indigenous species might reach Guam. Only two species have been recorded as having colonized Guam prior to World War II. Based on the available information, these introductions can be broadly classified as intentional or accidental. I herein report on these island records and the species' current status. There is a distinction made between those species released to establish populations (= intentional) and escaped/released pets or incidentally transported to Guam (= accidental).

Established Species

Bufo marinus (Marine Toad). Intentional. In 1937, a number of toads were released to control agricultural pests (Chernin 1979). Since then, the toad has spread island-wide and has reached sufficient densities to be regarded as a nuisance.

Litoria fallax (Eastern Dwarf Tree Frog). Accidental. In 1968, this species was first noted around the Won Pat International Airport. Eldredge (1988) speculated that this introduction was the result of escaped/released pets. At this time, the species has spread island-wide in association with wetlands.

Anolis carolinensis (Common Anole). Intentional. In the mid-1950's, anoles were introduced for insect control (Eldredge 1988). A second introduction of unknown magnitude occurred in the mid-1980's in the village of Mangilao. By the mid-1980's, this species had spread island-wide but is now restricted to urban situations due to predation by the introduced brown tree snake (*Boiga irregularis*). In October 1990, an adult male *A. carolinensis* was collected from the cargo hold of an aircraft where it had apparently survived a round trip from Guam to Indonesia.

Hemidactylus frenatus (House Gecko). Accidental. No date of introduction is known for this species, although Van Denburgh (1917) implied that it was present on Guam prior to 1906. At this time, H. *frenatus* is the most abundant gekkonid on Guam. It has been suggested that *H. frenatus* negatively impacts native gekkonids (Gibbons 1985; McKeown 1978; Zug 1991).

Carlia sp. (NCN). Accidental. No date of introduction is known for this species. The first specimens were collected on Guam in 1968. At this time, this species is the most abundant skink on Guam and occurs in all habitats. Coupled with habitat alteration, this species may be negatively impacting native skinks. Glen Ingram (pers. comm.) indicated that this species is unidentified although it most closely resembles *C. fusca*. A live specimen was observed (December 1991) in the passenger compartment of an aircraft outbound from Guam (R. Fisher, pers. comm.).

Boiga irregularis (Brown Tree Snake). Accidental. This snake was probably introduced on Guam shortly after World War II and has since spread island-wide reaching high densities (Rodda et al. 1992). Impacts on Guam have been substantial (Fritts et al. 1987; 1990; Fritts and McCoid 1991; in prep.; McCoid 1991; Savidge 1988). The snake is frequently encountered in port and airport situations and has been documented using surface shipping and aircraft to move to neighboring islands (Fritts 1987; McCoid and Stinson 1991).

Trachemys scripta elegans (Red-eared Slider). Accidental. Distributed in permanent bodies of water in south and central Guam (McCoid 1992a). Populations are probably the result of escaped/released pets.

Terrapene carolina triunguis (Three-toed Box Turtle). Accidental. Distributed in a few localities in central Guam (McCoid 1992b). If a population has been established, it is due to escaped/released pets.

Pelodiscus sinensis (Chinese Soft-shelled Turtle). Intentional. Established populations occur in southern (Inarajan area) and central (Fadian area) Guam. In the mid-1970's, attempts were made to commercially raise this species for local consumption and failure of these ventures resulted in this introduction. Reproduction has occurred in the southern population as a hatchling was observed in November 1990.

Status Unknown or Not Established

Kaloula picta (Narrow-mouthed Frog). Accidental. In 1990, a single specimen was retrieved live from the deck of a vessel just arrived from the Republic of the Philippines.

Pseudacris regilla (Pacific Treefrog). Accidental. In December 1989, a single live adult male was collected from inside a residence in central Guam. It is likely that this frog arrived on Guam from a recent shipment of Christmas trees from the U. S. Pacific Northwest.

Lamprolepis smaragdina (Green Tree Skink). Intentional. There was a failed attempt at introduction in the 1960's (Eldredge 1988). Reasons for failure may be related to the presence of the predatory *B. irregularis*. Successful introductions have been noted on Tinian and Saipan in the northern Mariana Islands.

Iguana iguana (Green Iguana). Accidental. In 1983 or 1984, an adult (1.8 m total length) was shot by a farmer in the Manengon Valley. Wildlife personnel on Guam had been receiving periodic reports of a "monster" sighted in cultivated areas. It is likely that this was an escaped/released pet that had been living on Guam for several years. The ability of this individual to persist on Guam is underscored by the establishment of this species in Hawaii (McKeown 1978). Identity of the specimen was verified by a photograph.

Gekko gecko (Tokay Gecko). Accidental. A single specimen was collected in 1983 from the U. S. Naval Magazine in association with palletized cargo from the Republic of the Philippines. Identity of the specimen was verified by a photograph.

Chrysemys picta elegans (Painted Turtle). Accidental. In 1990, a live individual was found in the passenger compartment of an aircraft. This was likely an escaped/released pet.

Emydid sp. Accidental. An unidentified species (not *Trachemys*) was captured in 1991 from central (Santa Rita area) Guam and inadvertently released before positive identification. It is likely that the presence of this species resulted from escaped/released pets.

Trionychid sp. Accidental. Sightings of a large soft-shelled turtle have been made in Fena Valley Reservoir in central Guam in

the late 1980's (G. Davis, pers. com.). Disk width places this species outside of the known disk range of the only other trionychid on Guam (*P. sinensis*).

The pre-western contact terrestrial herpetofauna consisted entirely of reptiles (*Varanus indicus, Ramphotyphlops braminus, Gehyra mutilata, G. oceanica, Nactus pelagicus, Lepidodactylus lugubris, Perochirus ateles, Lipinia noctua, Cryptoblepharus poecilopleurus, Emoia cyanura, E. caeruleocauda, E. atrocostata,* and *E. slevini*) (Rodda and Fritts 1992), but now includes additional elements such as freshwater turtles and amphibians.

Of the 17 extralimital species recorded on Guam, 14 are based on free-living individuals or populations. Nine of these species have become established on Guam. Of the four intentional introductions, three were successful. The non-marine herpetofauna of Guam now consists of 22 species (41% introduced). One of these introduced species, *Boiga irregularis,* has had a demonstrably negative effect on Guam's indigenous wildlife and two species (*Carlia* sp. and *Hemidactylus frenatus*) are suspected of negative impacts (Rodda and Fritts 1992). Three introduced species on Guam (*B. irregularis, Carlia* sp., and *Anolis carolinensis*), have historically demonstrated abilities to infest cargo and aircraft and potentially move to neighboring islands. As economic development and growth continues, the number of extralimital events in the Pacific Basin will also continue to grow. The establishment and devastation caused by *B. irregularis* on Guam is probably not going to be a singular event. It is likely that Saipan has an incipient population of *B. irregularis* and also has populations of *A. carolinensis, Carlia* sp., *Bufo marinus,* and *Trachemys scripta.* Tinian also has populations of *A. carolinensis, Carlia* sp., and *B. marinus.* Palau has an introduced unidentified *Carlia* and *B. marinus.* As a result of these and other faunal transplantation events, indigenous oceanic herpetofaunas are being replaced or augmented by widespread tramp species. Pacific island nations may wish to develop policies and techniques for the interdiction of non-native reptiles and amphibians. A number of U. S. federal agencies and U.S.-affiliated island governments have been cooperating in control of and containment policies and techniques for *B. irregularis,* and the Government of Guam no longer issues import permits for live reptiles or amphibians.

Acknowledgments.—I thank Herman Muna, Robert Anderson, Michael Ritter, and Gerald Davis of the Division of Aquatic and Wildlife Resources (Guam) for sharing information. Observations were contributed by Glen Ingram (Queensland Museum) and Robert Fisher (UC-Davis). R. Hensley, A. Bauer, and G. Rodda critically reviewed a draft of this manuscript. Research was supported in part by the U. S. Endangered Species Conservation Program, Project E-4.

Biology of Whiptail Lizards (Genus *Cnemidophorus*)

Biology of Whiptail Lizards (Genus *Cnemidophorus*), edited by John W. Wright and Laurie J. Vitt is a long-waited comprehensive treatment of an important, speciose, and widespread new world lizard genus. Growing out of a symposium held in 1984 at the University of Oklahoma, this useful volume has 15 chapters by virtually everyone who has worked on *Cnemidophorus* in recent times. Topics covered include genetics, endocrinology, activity metabolism, thermoregulation, foraging, life histories, reproductive tactics, hibernation, competition, comparative and community ecology, parthenoforms, evolution, phylogeny, and biogeography. This book is a must for all serious saurologists (students of lizards). Better place your order now as only 750 copies are being printed!

Biology, Status, and Management of the

Timber Rattlesnake

(*Crotalus horridus*):
A Guide for Conservation

William S. Brown

This long-awaited work sets the standard nationwide for conservation programs involving North America's pitvipers. Featuring sixteen stunning color photographs of Timber Rattlesnakes that demonstrate the extraordinary diversity of colors and patterns displayed by this variable species throughout its range, Brown's savvy approach to promoting the protection of this reptile is shown in the contents of this work, as follows: Introduction, Description, Distribution, Habitat, Ecology, Determination of Occurrence, Threats, Land Protection, Recovery Potential, Biological Monitoring Procedures, Biological Monitoring Programs, Research Needs, Research Programs, Management Procedures, Management Programs, Summary of Conservation Biology, Acknowledgments, and an extensive Bibliography. A must for anyone interested in venomous snakes and their conservation. Includes two exceptional line drawings by Donald G. Wheeler (cover) and John Lokke (frontispiece). vi + 78 pages. ISBN 0–916984–29–X. 1993.

Prepublication price $5.00 for SSAR Members After June 30, 1993 $8.00

Orders may be sent to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103 USA

(Include $1.00 for the first copy, and $0.50 for each additional copy to cover handling and postage)

TECHNIQUES

Tracking Hatchling Blanding's Turtles With Fluorescent Pigments

The early life history of hatchling emydid turtles is poorly documented (Iverson 1991) and practical and economical methods for demonstrating post-emergent behavior are generally lacking. In contrast with sea turtle species, studies of naturally incubated emydid and freshwater hatchlings in general have been limited to short-term, direct observation (Burger 1976) or manipulative field and laboratory studies with less than conclusive findings (Anderson 1958; Noble and Breslau 1938).

Blanding's turtles, *Emydoidea blandingi*, frequently nest from 0.1 to over 1 km from either their "home marsh" or other surface water (Congdon et al. 1983; Linck et al. 1989). We sought a method which would allow us to monitor the progress of hatchling Blanding's turtles away from protected, natural nests. Because we wanted to minimize disturbance to hatchlings, so as not to alter natural behavior, we utilized fluorescent powder demonstrated by ultraviolet light in darkness. Studies of a generally similar design have been successfully executed with adult tortoises (Blankenship et al. 1990), lizards (Fellers and Drost 1989) and rodents (Lemen and Freeman 1985).

Natural nests of *E. blandingi* in Massachusetts were protected shortly after completion with cylindrical vinyl-coated wire mesh cages (1 x 2.5 cm mesh). A circular trench was dug around each nest and a cage was placed in the trench (depth 30-45 cm) to discourage burrowing by predators. The trench was backfilled to ground level. Occasional diurnal soil temperatures taken 0.1 and 1 m outside the nest cages during incubation indicated soil temperatures inside and outside were identical.

Nests were checked for emergence at less than three day intervals beginning 15 August, 1990. Hatchlings of *E. blandingi* will burrow into the soil in the nest cage after emergence, presumably to avoid desiccation; often several individuals will be found dug in together (B. Butler, unpub. data). Hatchlings of other turtle species may not re-burrow after emergence (D. M. Carroll, pers. comm.), a fact that should be considered when using this technique. After the first *E. blandingi* emerged, we shaded remaining cages by placing weighted vegetation to one side of the cage roof.

All nests were monitored for hatchling emergence several times daily from 24 August through 16 September, 1990. Following emergence, hatchlings were measured (CL, PL) to the closest 0.1 mm with vernier calipers. Observation and tracking of hatchlings was performed continuously from 25 August through 18 September, 1990 and daily thereafter on a single, stationary hatchling until it was lost on 6 October following a 1 cm rainfall.

To avoid possible trauma due to marginal scute notching and its effect on behavior, we put indelible black ink marks on the plastron of each hatchling to identify its nest number utilizing plastral scutes in an additive numbering scheme. In this way, animals from different nests treated with the same color fluorescent pigment (see below) were distinguishable.

Hatchlings which had emerged and were active in nest cages from 0600-0900 h EDST were used experimentally for fluorescent-powder tracking. It was decided to do morning releases because hatchlings in nest cages were most active at this time of day and preliminary results indicated that they rapidly sought cover if released later in the day as ground temperatures increased. Emerged hatchlings which were inactive or reburied in the cages were removed, dusted, and released on subsequent mornings when active, or measured and released without being used experimentally. After being marked and measured, each animal was placed briefly in a canister of fluorescent powder (Radiant Color, Richmond, California). Colors used were the same as Fellers and Drost (1989). We attempted to avoid getting powder in the facial mucosa; the animals also tended to avoid this on their own. Pigment was rubbed lightly into the front leg scale beds as well as on the plastron and in leg pockets. Dusted animals were then placed (random orientation) next to the nest cage as the investigator moved away.

The typical initial hatchling response to the "dusting" treatment was to take several rapid steps after being placed down. This was followed by a variable period during which the animal appeared to look about prior to moving on. The dusting procedure did not seem to cause the animals distress and was presumed equivalent in terms of disruption of normal behavior to a hatchling stumbling over an obstacle in its path. Undusted, unnotched hatchlings released simultaneously with experimental animals did not show differential short-term behavior.

Hatchlings were allowed to travel undisturbed from release until after nightfall. Nocturnal tracking (after 2000 h) was then done with a long-wave (366 nm) ultra-violet lamp (model ML49, UVP, Inc., San Gabriel, California) and safety/UV-enhancing glasses (Fisher Scientific Co.). Experimental hatchlings were not exposed to white light at night, and we attempted to minimize their exposure to UV at close range. Depending on the number of extant hatchlings and their realized distance, tracking was continued as late as 0100 h. With this method observations were up to twelve hours out of phase with the actual movements of the hatchlings, which were essentially diurnal in this study.

Initial fluorescent tracking began at the nest (point of release) for "first day" animals, and subsequent trailing began at the point where the animal spent the previous night (generally an excavated or opportune form in the substrate). Following an individual trail only required minutes for short, readily discernible runs but took up to 2 h for extremely long or weak powder trails. Because of the variable time required to follow individual trails, and the variability in fluorescent powder trail quality, more animals were dusted and released than could possibly be followed by a single investigator using one UV lamp. Powder trails of poor quality were often abandoned in favor of those that could be followed with a reasonable effort or those in which considerable time had already been invested. With this strategy we were able to concentrate on animals which followed a variety of courses or behaviors and were able to minimize delays in the release of hatchlings from nest cages once emergence began.

Fluorescent plastic stake wire flags (Forestry Suppliers, Inc., Jackson, Mississippi) were placed in the ground at the beginning and end of a run as well as at points of significant behavior or course changes. Each flag was inscribed with date, time, nest number, release date, and fluorescent pigment color. Observer commentary was recorded on a portable cassette recorder. Distances and compass headings of hatchling movement were taken each morning from the flag positions. Compass headings were recorded in 22.5 degree increments (e.g., N, NNE, NE) and net straight line distance was measured using a 30 m tape.

Turtles which had been tracked to forms the previous evening were monitored periodically between 0600-1200 h so as to determine time and temperature of the ground when movement was resumed. Animals on the move whose trail was becoming difficult to read were given a second, superficial dusting with the same

color powder. In cases where the animal had not left its form by mid-morning a small amount of powder was sometimes placed at the entrance hole so the animal would walk through it on departure. Neither of these procedures seemed to distress hatchlings significantly but did make reading subsequent trails considerably easier. No turtles were disturbed while inactive in forms. Animals were tracked and monitored in this way over several days until they reached a wetland or became lost to the observer. Water temperature and habitat characteristics were noted at sites where animals entered water.

As noted by Fellers and Drost (1989), the blue pigment was the least easily demonstrated in trace quantities both due to its lower fluorescence and because many macro and microfungi and bacteria emitted similar color under UV. For this reason, blue was primarily used on initial releases to increase the number of animals we were able to track from one nest. Blue hatchlings were redusted with a different color while active if they became subject to prolonged tracking. The initial blue pigment was always readily detected on recolored turtles even after 10 days in the field, so recolored animals were not confused with other individuals.

Hatchling turtles undoubtedly retain less colored powder than do scaled night lizards (Fellers and Drost 1989), furred rodents (Lemen and Freeman 1985), or tortoises towing a reservoir of powder (Blankenship et al. 1990). Trail quality for our hatchlings was best on such substrates as loose sand or soil, mosses and lichens, leaf litter and grasses. Pigment deposition was reduced on hard-packed surfaces. Weak trails were particularly difficult to follow if the animal had traversed beds of brambles (*Rubus* sp.) or huckleberry (*Gaylussacia* sp.) because their low, dense foliage tended to reflect the UV light significantly, thereby interfering with readability of the powder trail. Full or near-full moon conditions also impeded trail reading in open moon-lit areas, and heavy morning dew also reduced trail quality. By using a large sample of animals without constraints as to their retrievability, we were able to offset their reduced pigment load capacity and their pigment loss resulting from minor fossorial activity. We found no evidence of predation on hatchlings due to their enhanced conspicuousness.

We considered alternative tracking methods including the use of radioisotope tracers (Bennett et al. 1970; Ward et al. 1976) and light-weight, short duration radio transmitters which are currently available. We feel that this economical but labor intensive method is more practical because radioisotope tracking requires special licensing, training, and equipment, and may be hazardous to subjects or investigators. Micro-radiotelemetry equipment is expensive and difficult to attach to hatchlings with certainty of not affecting natural behavior. Our method can be adapted to hatchlings of a number of turtle species and could be particularly useful with species which like *E. blandingi* may have nest site selection strategies (in terms of hatchling survival) which at our present level of understanding are unclear.

Acknowledgements.—We thank the management and staff of Great Meadows National Wildlife Refuge for permission and encouragement to perform this and related studies. We also thank Darlene Butler for field assistance throughout the nesting and tracking seasons, Gary Fellers for useful advice on methodology, and David M. Carroll for advice based on his experience with nesting and hatchlings of several New England turtle species.

Two New Simple Methods For Catching Small Fast Lizards

Methods commonly used to catch lizards include pit-fall traps, noose, and rubber bands (Simmons 1987). These methods are only partially successful with thin, small, fast-moving lizards such as *Cnemidophorus sexlineatus* and *C. hyperythrus* because these lizards seldom remain still and if they are noosed they can usually escape by slipping out of the noose. In recent studies on the endangered status of *C. hyperythrus*, a southern California coastal sage scrub dweller, it was essential to capture these lizards with efficiency (Brattstrom 1992; Rowlands 1992).

The first technique is similar to one first reported by Myers (1956) for use in collecting large fruit-eating teiids. A meal worm, or other insect, is tied on to monofilament line (4-pound test) by threading the monofilament end to end through the mealworm (Fig. 1). The loop can then be tied to a lizard pole (car or other radio antenna) and dangled in front of a lizard. When the lizard bites the mealworm the loop is flipped into the air. Usually the lizard stays on the mealworm; occasionally it lets go and it is necessary to catch the lizard in the air as it falls. Note that the lizard is not noosed, but rather it bites and holds on to the mealworm. With practice in catching hundreds of lizards we now have a 93% efficiency with *Cnemidophorus hyperythrus*. The technique works well with *C. tigris*, *Sceloporus*, and *Uta*. The dangling worm is also useful in luring crevice-dwelling lizards, such as *Sceloporus orcutti*, out of a crevice where they can then be caught by noosing. The meal worm

can be used over and over again. It is necessary to replace the meal worm only about every half hour.

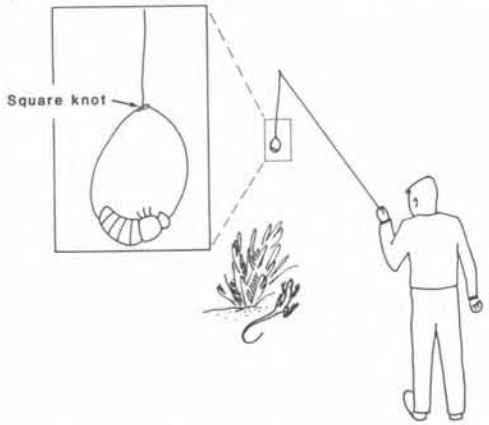

FIG. 1. Drawing showing method of catching lizards by tying an insect onto a loop. When a lizard bites the insect, the pole is jerked upward.

The second technique is to trap lizards in tubes placed near bushes. Lizards are purposefully chased into and then out of a bush. In the meantime, plastic or cardboard tubes, taped shut at one end, are placed on the opposite side of the bush (Fig. 2). Lizards leaving the bush apparently see a dark, hole-like place in which to escape and run into the tube where they can be removed easily. We use tubes of all lengths, diameters, and materials. PVC plastic pipe covered at one end with duct tape is especially useful. The method is most effective in open, flat areas and least effective in rocky areas where a lizard has more choices of escape routes.

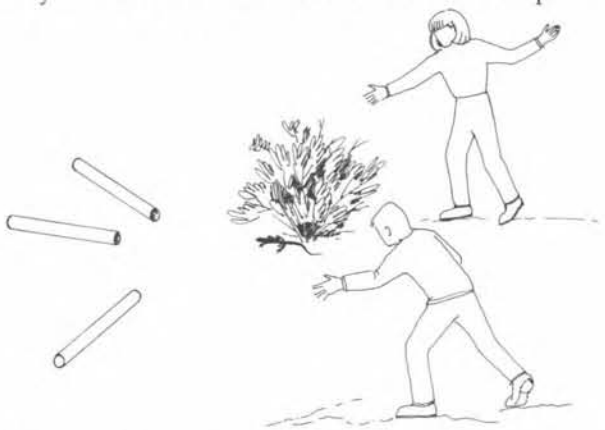

FIG. 2. Drawing showing method of catching lizards by chasing them into tubes placed behind a bush. Tubes have one end covered with tape.

Acknowledgments.—Drawings were done by Candace Irelan and the methods were developed under a California Department of Fish and Game contract (FG8597).

Differential Retention Of Metal And Plastic Tags On The Black Sea Turtle (*Chelonia agassizi*)

Sea turtles are commonly marked with plastic or, more frequently, metal flipper tags. Tag loss is an unresolved problem that renders tagging efforts ineffectual and hinders the collection of data relating to various aspects of sea turtle natural history (Balazs 1982; Green 1979; Mrosovsky 1983). Tag retention may be affected by one or a combination of the following factors: the species of sea turtle, the type of tag used, the method of application, the flipper selected for application, the place of application on the flipper, and even the oceanic region frequented by the tagged individuals (see Mrosovsky 1983, for review).

In 1978, the Mexican Instituto Nacional de la Pesca (INP) in coordination with K. Cliffton of the Arizona-Sonora Desert Museum began the first systematic black turtle (*Chelonia agassizi*) conservation and research project at Colola and Maruata Bay in Michoacan, México. (Some consider the black turtle to be a subspecies of *Chelonia mydas*. We consider the black turtle to be a separate species and refer to it as *Chelonia agassizi* following Bocourt 1868). In 1982 the Universidad de Michoacan initiated a tagging program to assess nesting periodicity, fecundity, philopatry, and long distance movements of black turtles nesting on Colola beach.

We compared retention rates of plastic and metal tags applied to different flippers, in order to assess the effect of type of tag and flipper selected for application on tag retention in the black turtle. One hundred thirty-one nesting females were double tagged (one plastic and one metal tag) in 1988 (46) and 1989 (85) at Colola beach. Metal and plastic tags were assigned to the flippers randomly, as follows: left foreflipper: 36 metal, 36 plastic; right foreflipper: 33 metal, 29 plastic; left hindflipper: 27 metal, 46 plastic; right hindflipper: 35 metal, 20 plastic. Tags were of two types: monel size-l9 tags (National Band and Tag Co., USA); and plastic (41 mm x 35 mm, Allflex Tag Co., USA). On the foreflippers tags were placed on the trailing edge of the second or third proximal scute. On the hindflippers tags were placed on the trailing edge of the flipper proximal section. Both plastic and metal tags were clinched using standard tagging pliers, and flippers were not prepunched before tagging. Both types of tags had an identification number and a return address engraved on them.

Gravid black turtles deposit as many as seven clutches per season at about 12-14 day intervals (Alvarado and Figueroa 1989). Therefore, tag status was monitored continually throughout the season. During the 1988 and 1989 seasons (September-January), the 4.8 km nesting beach at Colola was patrolled on foot nightly

(2000-0530 h). In most cases turtles were tagged immediately after nesting.

The differences between the expected and observed tag loss for plastic and metal tags, and for each type of tag on the four flippers were tested using a G test (Sokal and Rohlf 1979). For all mean values a ± SE was estimated.

Of the 131 turtle double-tagged in 1988 and 1989, 113 (86.3%) were sighted at least once during each season. The average number of resightings per turtle was 3.6 ± 1.7 (range 1- 8). The average number of days between initial tagging and the first resighting was 28 ± 2.6 (range 0-83). The total number of tags lost from resighted individuals was 33 (29.2%) for metal and 6 (5.3%) for plastic (Table 1). The difference in performance between plastic and metal tags was significant (Gadj. = 18.92, 1 df, P<0.001). The difference in loss rate among the four flippers (Table l) was not significant for either the metal (G = 6.05, 3 df, P>0.05), or plastic tags (G = 4.49, 3 df, P>0.05).

Sea turtles lose monel metal flipper tags for several reasons, including tissue necrosis, abrasion, tearing, and faulty application (Balazs 1982). In the present study, the primary cause of loss of metal tags appeared to be tissue swelling around the tag, which may have resulted in the unclinching of the tags. Tissue necrosis and enlargement of the placement hole, common in the leatherback (*Dermochelys coriacea*) (Eckert and Eckert 1989), was seldom encountered in the black turtle. The high loss rate of metal tags within a season suggests the possibility of improper tag application as another cause of metal tag shedding. Because the thick, muscular foreflippers were not prepunched, it is possible that some of the metal tags did not lock properly. However, fleshy areas too thick to accommodate the locking mechanism of the tag were avoided. Furthermore, metal tags were shed independently of the flipper selected for placement.

TABLE 1. Metal and plastic tag loss rate. The difference in loss rate between plastic and metal tags was significant. The difference in loss rate among the four flippers was not significant for either the metal or plastic tags.

Location of Tag Application	Number of Tags Applied		Number of Tags Lost	
	Metal	Plastic	Metal	Plastic
Left Foreflipper	36	36	9	1
Right Foreflipper	33	29	12	2
Left Hindflipper	27	46	3	3
Right Hindflipper	35	20	9	0
Totals:	131	131	33	6

Double tagging of black turtles in the Galapagos Islands has also shown that plastic tags had better retention than metal tags. Green (1979) reports a 42% loss of monel tags and a 7% loss of plastic tags over a period of four years for 116 recaptured turtles.

The main problem with the use of plastic tags on the black turtle in this study was the obliteration of the numbers and legends embossed onto the tags due to abrasion and/or algal growth. Green (1979) reports a similar problem with the plastic tags used in the Galapagos Islands. Legibility of the numbers and address on the plastic tags used in Michoacan has been improved in recent years with deeper etching of numbers and letters, readable even when the color of the writing has faded or abraded away.

The results of our double-tagging study indicate that plastic tags are retained better than monel metal tags by the black turtles in the east Pacific, independent of the flipper selected for tag application. The possible effects of prepunching of the flipper before tag application are currently being evaluated.

Acknowledgments.—Data presented in this paper are part of the project "Population Recovery of the Sea Turtles of Michoacan, México: An Integrated Conservation Approach" funded by U.S. Fish and Wildlife Service, World Wildlife Fund, and the Universidad de Michoacan. We thank K. Cliffton, R. Marquez, J. Woody, and R. Byles for their valuable suggestions regarding field research and conservation activities. P. Dutton critically read the manuscript. HERPETOLOGICAL HUSBANDRY

Courtship Behavior And Oviposition Of Captive *Acanthochelys pallidipectoris* Freiberg

Acanthochelys pallidipectoris (formerly *Platemys pallidipectoris*; usage following McBee et al. 1985 and Iverson 1992) is a pond turtle from the Chaco region of northern Argentina, Paraguay, and Bolivia (Ernst 1983; Ernst and Barbour 1989; Iverson 1992). The reproductive biology of the species is poorly known and courtship behavior is undescribed. Freiberg (1945), in describing this species, reported that it laid eggs on mud and sand banks. Richard (1991) described deposition of eggs by a wild-caught female. Here I describe the courtship and oviposition of a wild caught adult pair (male 133 mm straight-line CL, 325 g; female 137 mm straight-line CL, 402 g) of unknown origin, obtained via the pet trade in June, 1987.

The turtles were housed in a 1.2 m by 1.2 m fiberglass bin. Three quarters of the surface area was water and the other quarter a nesting area of mixed sand and topsoil. Turtles were fed live fish, beef, poultry, newborn mice, tadpoles (*Hyla chrysoscelis*), and mealworm larvae. Beef, chicken hearts, and mice were most readily eaten; other foods were accepted less often. Floating aquatic plants were provided, but were used as shelter rather than food.

Courtship behavior was first observed in early September 1990, and courtship activity continued sporadically until late November of that year. Male courtship behavior consisted of approaching the female from the rear with his head and neck extended across the length of the female's carapace. He then rubbed his head and neck back and forth on her carapace, while trying to maneuver the female into a position where he could more easily mount. Once mounted, he grasped the rim of the female's carapace with all four feet and began prodding her head and neck with his face, until the female folded them beneath her carapace. This made the female's vent more accessible. The average time of individual courtship behavior was thirty minutes, but ranged from fifteen to ninety minutes. Courtship was stimulated by a change of water in the enclosure.

Oviposition first occurred on 18 November 1990, when one egg was laid in the water. Two weeks later a second egg was also deposited in the water, and on 9 March 1991, a third egg was found in the water. This last egg was possibly retained by the female from an earlier clutch (Table 1). The eggs were incubated on damp vermiculite at 30°C. The incubator consisted of a Styrofoam box (30 x 30 x 20 cm). Temperature was maintained by an aquarium heater submersed in a container of water. All eggs were nearly spherical, chalky white, and brittle-shelled with small white crystal points dispersed over the surface. Within a few weeks, the eggs turned yellow and emitted a strong sulfurous smell, indicating spoilage, and no signs of embryonic development were visible by candling. The eggs were opened and shell thickness was measured (0.4 mm).

Courtship was again observed in the fall of 1991. The female was routinely palpated for the presence of hard shelled eggs. On 16 December 1991, 10 U.S.P. units of oxytocin were injected to induce oviposition; two eggs were laid 3.5 h later. After 83 days of incubation, small cracks appeared on the egg shells. The eggs were then opened, but no embryonic development had occurred. Presumably the eggs were infertile.

TABLE 1. Egg morphometrics of *Acanthochelys pallidipectoris*.

Oviposition Date	Length (mm)	Width (mm)	Weight (g)
18 Nov 1990	26	23	8.2
2 Dec 1990	25	22	8.1
9 Mar 1991	26	22	8.5
6 Dec 1991	28	23	9.2
6 Dec 1991	28	24	9.4

Iverson (pers. comm.) reports that "four eggs (averaging 24.5 X 22.2 mm) were laid in December 1991 by one or more of six captive females that averaged 144 mm CL and 369.2 g." Richard (1991) reported that on 26 September 1990 an adult female (159 mm CL and 400 g) laid five eggs (averaging 24.8 X 23.7 mm and 8.8 g).

Acknowledgments.—Thanks are due to Robin M. Andrews for her support and help with this project, and to Carl H. Ernst for his discussions and help with the revision of the paper, and J. B. Iverson for his personal communication.

An External Support Device For Turtle Skull Repair

Many turtles are injured by roadside and recreational accidents (Bury 1978). Shell injuries have been repaired with various materials (Frye 1981). Leg injuries have also been treated successfully (Frye 1981). Skull injuries largely have been neglected because of the lack of a method of stabilizing the skull during recovery. The construction of a simple, external, supportive mask will often allow full recovery. Four turtles with similar head injuries have successfully recuperated under my care using this method.

The exemplary case involved a female *Terrapene carolina bauri* that was hit by a car on 12 July 1990. Injuries included minor abrasions to the plastron and carapace, and a broken plastral hinge. The mandible and maxillae were each fractured in three places. Other fractures occurred in the hyoid apparatus, premax-

illa, jugal, and quadratojugal. The limbs were not harmed. The turtle was examined immediately after the accident. Breathing was accomplished through the mouth, and coagulated blood appeared at the nares posterior to the angle of the mouth. The turtle could walk, although she favored the right foreleg. Dexamethasone $NaP0_3$ at the dosage of 0.125 mg/kg (all dosages found and modified from Jacobson et al. 1983, except for triamcinolone acetonide, succinyl choline chloride, isofluorane, and oxytocin) was administered intramuscularly in the rear leg to reduce swelling and discomfort, and surgery was scheduled for the next day.

The turtle was anesthetized with 20 mg/kg ketamine HCl and 3 mg/kg diazepam intramuscularly, and 0.5-1.0% isofluorane gas administered via a small mask crafted from an empty 10 ml plastic syringe cover. Intubation was not possible because of the injuries, so breathing was monitored visually, and the mouth was kept clean and dry with sterile cotton swabs. The skull bones were manipulated into an anatomically correct shape.

The upper part of the mask that crosses the skull was constructed from a single piece of 21 gauge stainless steel wire, and the heavier wire yoke encircling the lower part of the skull was made from 18 gauge wire (Fig. 1). The joints between the wires were twisted tightly, and the mask was anchored directly to the skin with cyanoacrylate. Other wires can be added to support specific areas depending on the damage. Radiographs taken before the turtle attained full consciousness revealed a fracture between the right scapula and postscapula which resulted in a right forward limp. Three eggs (ca. 3.6, 3.8, and 4.1 cm long) were clustered just anterior to the pelvis. The skull appeared stable except for spaces between the premaxillae and maxillae that may have been caused by swelling.

The manipulations produced blood loss and symptoms of shock. A lactated ringers solution was administered intraperitoneally to improve fluid volume and electrolyte balance. Dexamethasone $NaP0_3$ 0.125 mg/kg and triamcinolone acetonide 0.07 mg/kg (dosage modified from Kirk and Bistner 1981) were injected intramuscularly to reduce swelling and discomfort. The effects of triamcinolone acetonide last several times longer than that of dexamethasone. The turtle was observed often for infections during convalescence because anti-inflammatory drugs are known to compromise the immune system.

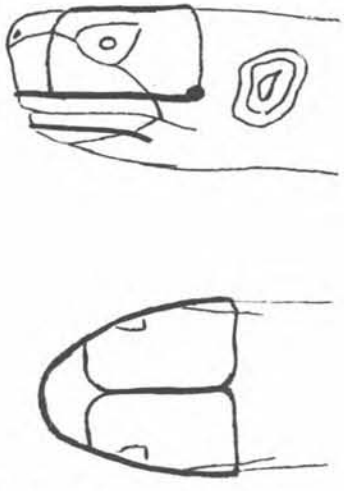

FIG. 1. Lateral and dorsal views of the wire mask used to support the turtle skull during convalescence. An optional brace on the lower jaw is also shown.

Gentamicin sulfate at a dosage of 5.0 mg/kg injected intramuscularly on the first day after surgery was continued at 2.5 mg/kg every 72 h for 10 days, and ampicillin at a dosage of 3.0 mg/kg was given orally once daily for 14 days. The turtle was tube-fed a mixture of three parts strained fruits and vegetables and one part strained chicken. A maximum of 10 g were taken per feeding. The eggs were aborted with oxytocin at a dosage of 5.0 units intramuscularly one month after surgery (dosage modified from Kirk and Bistner 1981). They were considerably smaller than recorded in the radiographs, and an attempt to incubate the eggs was not successful.

The turtle was kept in a terrarium at 30°C with a 12:12 LD cycle throughout the winter. The mask fell off after six months, and the skull appeared reasonably stable. The turtle ate on her own for the first time nine months after the accident and gained 112 g in the next 63 days. She was released 11 months after the accident.

Time and energy are the main concerns for successful completion of such a project. Presurgical radiographs would have increased the finesse of the operation. Anesthesia would have been more effective if succinylcholine chloride at a dosage of 0.25-0.5 mg/kg intramuscularly had been used in conjunction with ketamine HCl, but the dosage must be monitored carefully to avoid respiratory distress (Page and Mautino 1990). Cyanoacrylate should be used in a well ventilated area, and intubation should be used when possible to isolate the fumes from the patient.

Products Mentioned.—Ampicillin: Beecham Laboratories, P.O. Box 7929, Philadelphia, Pennsylvania 19101; Cyanoacrylate: Loctite Corp., Cleveland, Ohio 44128; Dexamethasone $NaP0_3$: Anthony Products Co., Arcadia, California 91006; Diazepam: Steris Laboratories, Phoenix, Arizona 85043; Gentamicin sulfate: Schering Corp., Galloping Hill Rd., Kenilworth, New Jersey 07033; Isofluorane: Anaquest Inc., 110 Allen Rd. Box 804, Liberty Corner, New Jersey 07938; Ketamine hydrochloride: Fort Dodge Laboratories Inc., Fort Dodge, Iowa 50501; Stainless Steel Wire: National Keystone Products, 616 Hollywood Ave., Cherry Hill, New Jersey 08002; Succinylcholine Chloride: Burroughs Wellcome, 3030 Cornwallis Rd., Research Triangle Park, North Carolina. 27709; Triamcinolone Acetonide: E.R. Squibb & Sons Inc., P.O. Box 5250, Princeton, New Jersey 08543.

Survival, Weight Changes, And Shedding Frequencies Of Captive Scarlet Snakes, *Cemophora coccinea*, Maintained On An Artificial Liquid Diet

The difficulties of keeping many species of small snakes in captivity are well known. One of the problems most frequently encountered involves inducing such snakes to feed voluntarily on a diet which is both readily obtainable and capable of maintaining the snakes in good health over extended periods of time.

Although found throughout much of the southeastern United States and abundant in some parts of its range, the scarlet snake (*Cemophora coccinea*) has been relatively little studied, as a result of its secretive and semifossorial habits (Conant and Collins 1991; Nelson and Gibbons 1972; Palmer and Tregembo 1970; Williams and Wilson 1967). This species has seldom been kept or studied under captive conditions for extended periods of time, due primarily to its refusal to feed voluntarily on any of a number of types of food (Snyder 1945). It has been suggested that reptile eggs may form an important part of the diet of the scarlet snake (Dickson 1948; Minton and Bechtel 1958; Neill 1951; Williams and Wilson 1967). Palmer and Tregembo (1970) described the presence of what appeared to be solidified egg yolk in the stomachs of several preserved specimens, and described the feeding behavior of several captive scarlet snakes which were successfully offered the eggs of other snakes.

On the basis of these reports, and because of the difficulty of obtaining a ready supply of small reptile eggs to serve as food, we attempted to determine whether captive scarlet snakes could be maintained in good health on a liquid diet formulated from the yolk of chicken eggs. We report here the maintenance of several scarlet snakes on such a diet for periods ranging up to nearly 1.5 years in captivity. Data on body weight and shedding frequency are also provided for these individuals as a further indication of the ability of this feeding program to maintain these captives in good health, as well as to provide some additional basic biological information for this relatively little-studied species.

Scarlet snakes were collected on the United States Department of Energy's Savannah River Plant (SRP) near Aiken, South Carolina. Snakes were collected either crossing highways in the evening or in drift fence pitfall traps (Nelson and Gibbons 1972). Since snakes which died shortly after capture may have been injured prior to collection, data were excluded from any snake which did not survive at least 6 weeks after capture.

Twelve snakes were maintained under approximate temperature conditions of 18-20°C in a laboratory where they were exposed through a nearby window to the natural photoperiod for west-central South Carolina, with the exception of occasional instances when laboratory work required that lights be turned on in the room for several hours at night.

Snakes were housed in 3.8 liter glass jars which were filled to a depth of approximately 6 cm with dry pine or hardwood shavings. No drinking water was provided in the jars in which the snakes were housed. Three days per week (Monday, Wednesday, and Friday), snakes were removed and placed in smaller glass jars (approximately 0.5 liter) into which a liquid food mixture was poured to a depth of approximately 3-5 cm. The feeding mixture was prepared fresh each day by thoroughly mixing approximately equal amounts of separated chicken egg yolks and tap water which was slightly warm to the touch. A soluble commercial poultry vitamin powder (Vita-Lizer, Vineland Laboratories, Vineland, New Jersey) was stirred into the mixture at approximately 1-2 g per 500 ml.

Snakes were allowed to soak in the liquid food mixture for 1-2 hours. They were then rinsed with tap water and returned to their housing jars. Since snakes had no access to water other than when soaked in the liquid food mixture, all individuals drank the mixture readily soon after being placed in the feeding jars. It was imperative to handle the snakes gently after removing them from the feeding jars since rough handling at this time often caused them to regurgitate.

Body weights of each snake (± 0.1 g) were determined immediately prior to the first feeding of each week, and snout-vent lengths were measured (± 1 mm) at capture, by gently but firmly stretching the snake's body along a metric ruler. Snout-vent lengths and weights were also determined at the end of the period of captivity for five of the individuals. Statistical analyses were conducted using the Statistical Analysis System (SAS) procedures (Barr et al. 1976).

Of the 12 snakes, 2 escaped following failure to properly tighten the lids on their feeding jars, and 2 were released in good health at the end of the study. The remaining 8 snakes died after periods ranging from 66 to 536 days in captivity ($\bar{x}$ = 171 days). However, all but two of these snakes had increased in weight from the time of their capture, three more than doubling in body weight. Of the 5 individuals whose length and weight were recorded both at the time of capture and again at the end of the period of captivity, 4 showed increases in their weight/length ratios, during captivity, while one showed a very slight decrease (Fig. 1).

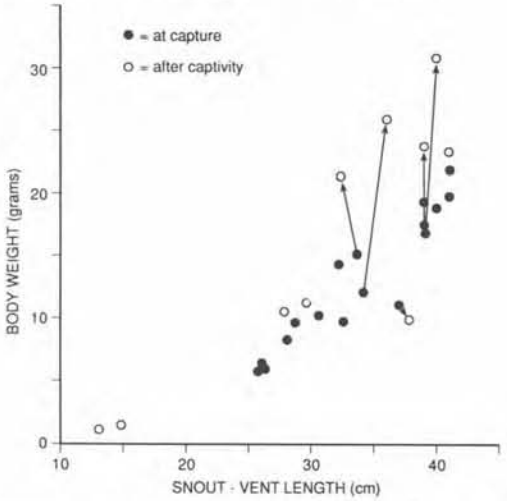

FIG. 1. Relationship between snout-vent lengths and body weights of wild-caught and captive scarlet snakes. Data for captives were based on final body weights and measurements taken after maintenance on an artificial liquid diet. Arrows connect points representing the same individual. This figure includes data for several wild-caught snakes in addition to the 12 snakes used in the present feeding study. No final length data were available for two captives that escaped unexpectedly and five of the captives were not measured at the time of capture.

Body weight changes of the captive snakes maintained on the liquid diet are summarized in Fig. 2. Only 2 of the 12 snakes studied lost weight on the liquid diet and 2 others gained less than 10% of their initial weights at capture. Of these 4 snakes, 3 were small juveniles (capture weight < 3.5 g), and all 4 snakes which showed low or no body weight gains did not live long in captivity (66-167 days). Of the 8 snakes that died in captivity, all but the 2 smallest juveniles showed initial weight gains, followed by subse-

quent weight losses, often immediately prior to death (Fig. 2). Regression analyses indicated that in the case of every snake but 2 (snakes #5 and #10, Fig. 2), there were highly significant ($P \leq 0.0003$) overall increases in body weight with increasing time in captivity. Coefficients of determination (r^2) ranged from 0.21 to 0.90. Low coefficients of determination were generally associated with snakes which first gained and then lost large amounts of weight immediately prior to their death. Overall weight gains ranged from 0.0015 to 0.12 g/day and averaged 0.042 g/day for the 10 snakes which showed significant regressions of body weight against time in captivity.

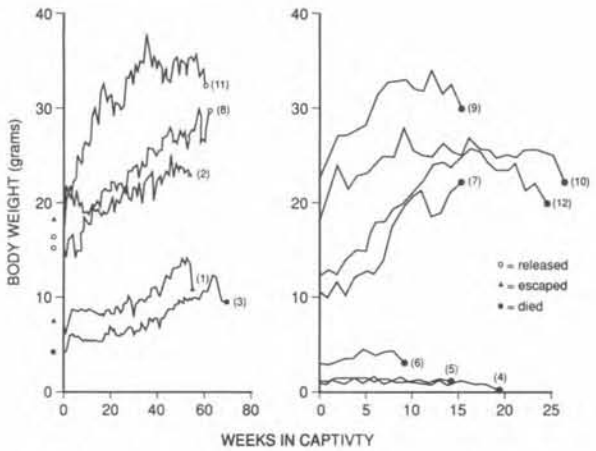

FIG. 2. Body weight changes of captive scarlet snakes maintained on an artificial liquid diet. Numbers in parentheses designate individual snakes as referred to in the text. Symbols to the left of the vertical axis are provided to aid in the identification of the origin of each individual's curve. Data are presented in two graphs in order to provide clearer representations of the weight changes of individual snakes.

The time intervals which elapsed between successive sheddings of the captive snakes are presented in Fig. 3. The frequency distribution of shedding intervals was skewed, with no tendency to show a bimodal distribution suggestive of either skipped or unobserved shedding events. Although the smaller snakes tended to show shorter intervals between sheddings (e.g., average intervals = 12 and 14 days respectively, for snakes #4 and 5 (Fig. 2), there were no significant relationships between either average snout-vent lengths or average body weights during a shedding interval and the duration of that interval. Thus, there was no significant tendency for larger and more slowly growing snakes to shed at different rates from those that were smaller and growing more rapidly ($F = 0.09$; $df = 1, 90$; $P = 0.77$, and $F = 0.49$; $df = 1, 90$; $P = 0.49$, for snout-vent length and body weight, respectively). An analysis of variance indicated that intervals between sheds were significantly shorter in winter months (Nov.-Feb.; $\bar{x} = 22.3 \pm 1.86$ (SE) days, $N = 37$) than in summer months (May-Aug.; $\bar{x} = 31.5 \pm 2.49$ (SE) days, $N = 25$) ($F = 8.70$; $df = 1, 60$; $P = 0.004$).

Except for the fact that the yolks of chicken eggs were used instead of reptile eggs to prepare the liquid diet, the feeding regime used in this study may not have been entirely "artificial." The published descriptions of feeding habits of this species (e.g., Palmer and Tregembo 1970) describe it as piercing eggs and consuming the yolk and contents in a manner similar to that employed by the snakes in drinking the contents of their soaking jars in our study. It is possible that a less dilute mixture of egg yolk and water or perhaps homogenized whole eggs including whites and yolks, might have proved even more satisfactory and might have reduced mortality even below that reported here.

The weight gains shown by the snakes in this study, 5 for periods of a year or longer (Fig. 2), clearly suggest that the liquid diet provided a generally adequate plane of nutrition and, under appropriate conditions, could provide a basis for the long-term captive husbandry of this species and perhaps other forms of small egg-eating snakes. Of key importance to our procedures however, was the provision that the snakes never be given access to drinking water except when soaking in the liquid diet. In earlier attempts to develop this technique, snakes which had access to drinking water at all times seemed agitated and seldom consumed much of the liquid diet when moved to the smaller soaking jars.

Several of the snakes in the present study whose body weights showed evidence of reaching asymptotes (snakes #2, 8, and 11; Fig. 2) had snout-vent lengths of 41.1, 33.9, and 40.2 cm, respectively. These exceeded the average of 30.2 cm reported by Nelson and Gibbons (1972) for a sample of 62 wild-caught scarlet snakes from the same area from which the snakes used in this study had been collected. The tendency of the body weights of such individuals to level-off during our study may thus have been due to their beginning to reach their genetic potential for adult body size.

Snider and Bowler (1992) present two records for captive longevity which exceed those periods of captive maintenance reported here for this species (2 years 10 months for *Cemophora coccinea coccinea*, and 4 years 10 months for *C. c. copei*). Information provided by the individuals maintaining the snakes which set these records indicated that in both cases the snakes involved were kept on feeding regimes similar to that described in the present study. In both instances, the snakes were maintained solely on a liquid diet of chicken eggs which one individual ingested voluntarily, and which in the other case had to be force-fed to the snake (J. Beane and D. C. McIntyre, pers. comm.).

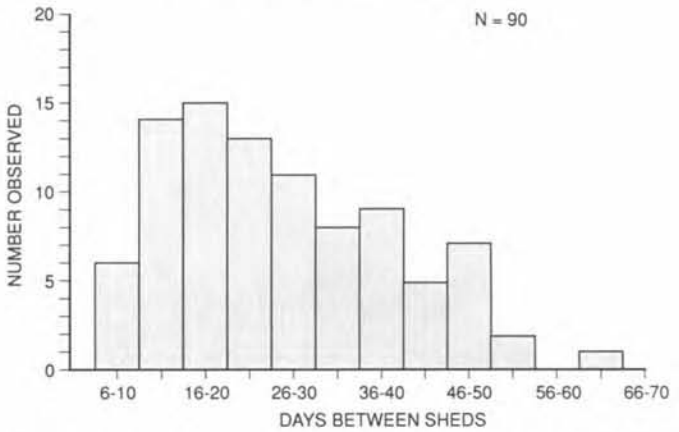

FIG. 3. Frequency distribution of elapsed times between successive shedding events of captive scarlet snakes maintained on an artificial liquid diet.

Our data suggest that the larger the snake, the more likely it would be to thrive on the artificial diet, suggesting in turn that some component of the diet may have been inadequate for the smaller individuals. It is also possible that being deprived of *ad libitum* drinking water, the higher surface-to-volume ratio of the smaller snakes may have resulted in excessive dehydration which would have required soak-feedings at a higher frequency than three times per week. Very small specimens of this species are probably not capable of piercing and drinking the contents of most reptile eggs and natural dietary habits of such smaller specimens may differ from those of the adults. Snakes #4, 5, and 6 (Fig. 2) were captured in August and September and were probably hatchlings of the year (snout-vent lengths all less than 15.0 cm; Woolcot 1959).

The tendency of 4 out of the 5 individuals, for which initial weight/length data were recorded at capture, to increase these ratios during captive maintenance (Fig. 1), was suggestive of these snakes' ability to thrive on the artificial liquid diet. The average weight gains shown by the scarlet snakes on this diet represented as much as 0.80% body weight gain/day (snake #7, over a 15-week period; Fig. 2) and averaged 0.27% body weight gain/day for the 10 snakes which showed significant regressions of body weight against time in captivity. This value is close to the 0.36% body weight gain/day calculated from data for captive-reared *Spalerosophis cliffordi* provided by Dmi'el (1967), and is much higher than gains of 0.002-0.093% body weight/day, calculated from data for wild *Lampropeltis triangulum* (Fitch and Fleet 1970). Both of these latter studies dealt with snakes of approximately the same body size as the *Cemophora* used in the present study.

The failure of shedding intervals to change with increasing body size of the scarlet snakes suggests that the process of ecdysis in this species may involve more than the replacement of the epidermis in order to accommodate an increasing body size. Otherwise, shedding intervals should have been lengthened as the snakes' growth slowed at the larger body sizes. However, data presented by Cliburn (1976) indicate that under some circumstances more rapidly growing snakes may have shorter shedding intervals. Munro (1952) indicated that there may be significant differences in the shedding intervals of different species of snakes even when maintained together under the same captive conditions. The shedding intervals reported here for the scarlet snakes tended to be shorter than most of those reported for other species. The tendency of our data to show a skewed distribution suggests that simple comparisons of average shedding intervals may not be meaningful.

In conclusion, the data presented here show that some individuals of *Cemophora coccinea* can be maintained in captivity for extended periods of time on an easily prepared artificial liquid diet. Since food intake could also be readily quantified by analyzing the nutrient and energy content of the liquid diet and weighing the snakes immediately before and after their feeding soaks, data on nutrition, energetics, and contaminant cycling could easily be collected using these procedures. Despite being considered one of the most difficult of small snakes to maintain in captivity, with further refinements of the procedures described here, *Cemophora coccinea* could possibly become a useful laboratory model for studies of many aspects of the general biology of the smaller snakes.

Acknowledgments.—The patient and careful assistance of Mrs. R. Anderson, P. E. Johns, and M. J. Vargo in caring for the snakes is gratefully acknowledged, as is the assistance of the late G. Knighton who, along with various members of the Savannah River Ecology Laboratory staff, helped to provide snakes for the study. The authors are grateful to J. Beane and D. C. McIntyre for sharing information on their husbandry techniques for this species. J. D. Congdon, W. E. Cooper, and L. J. Vitt provided critical readings of this manuscript, while helpful editorial assistance was provided by J. D. L. Mayer and drafting services by J. Coleman. This work was supported by a contract (DE-AC09-76SR00-819) between the Institute of Ecology of the University of Georgia and the U.S. Department of Energy. Portions of final data analyses and manuscript preparation were undertaken while the senior author was a visiting scientist at the Duke University Marine Laboratory.

RECENT POPULATION CHANGES

Recent Population Changes provides an outlet for anecdotal or minimally documented information on local extinctions or regional population changes. These reports could be valuable historic indications that might enhance our understanding of very long term (>20 yrs) population trends and changes in distribution patterns.

Manuscripts should be submitted directly to the editor of this section: Ralph W. Axtell, Department of Biological Sciences, Southern Illinois University, Edwardsville, Illinois 62026, USA.

Possible Decline Of *Xenopus* Populations In Southern California

The African clawed frog (Pipidae: *Xenopus laevis*) has been a common southern California amphibian for more than twenty years. During this period, populations were recorded and studied from many drainages in Los Angeles, Orange, Riverside, and San

Diego counties (McCoid 1976, 1985; McCoid and Fritts 1980a, b, 1989, in press; St. Amant and Hoover 1969; St. Amant et al. 1973).

On 29 and 30 June 1992, we visited known sites of former *Xenopus* occurrence in San Diego and Riverside counties. These sites had harbored dense populations in the past, but some had not been surveyed since the late 1970's or the mid-1980's. Survey techniques consisted of visual observations and dip-netting. Drainages surveyed (San Diego Co.) were Sweetwater River, Tijuana River, Tecolote Canyon, and (Riverside Co.) Santa Margarita River (=Arroyo Seco Creek). Additionally, the stream below Lake Murray Reservoir (San Diego Co.) was surveyed in 1990.

Adequate aquatic habitat was present at most sites with the exception of one in the Sweetwater River drainage (Avocado and Valencia Streets) and Arroyo Seco Creek (Riverside Co.). The site in the Sweetwater drainage had been dry for a number of years and Arroyo Seco Creek (upstream from a known occurrence site) was dry. While the actual site in Riverside Co. was not surveyed, the creek above the site was flowing during *Xenopus* investigations in the late-1970's. This site was, however, trapped in 1989 and no frogs were collected (R. Tinsley, pers. comm.). No *Xenopus* were observed at any of these sites.

It is unlikely that *Xenopus* has been extirpated from many sites in southern California. Had successful reproduction occurred, however, dip-netting and visual observations should have yielded either larvae or recently metamorphosed frogs at the localities we surveyed (see McCoid and Fritts 1989 for a discussion of seasonal reproduction). More likely, frog populations have declined and there was little or no successful reproduction at the surveyed sites in 1992, despite above normal rainfall the previous winter. There are several 1992 anecdotal (but reliable) reports of adult *Xenopus* in both the Sweetwater drainage and Otay Mesa area (San Diego Co.).

Reasons for the apparent decline may be due to the extended drought in southern California from 1987 to 1991 which probably inhibited successful reproduction and recruitment. Additionally, at one site that maintained adequate habitat (Tijuana River), predaceous centrarchids (*Micropterus salmoides*) were observed. Predaceous fishes may control larval populations of *Xenopus* (McCoid and Fritts 1980a; Prinsloo et al. 1981).

Acknowledgements.—We thank R. Tinsley for sharing his observations on the Riverside Co. population. R. Hensley reviewed a version of the manuscript.

LIFE HISTORY NOTES

Life History Notes is analogous to Geographic Distribution. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword which best describes the nature of their note (e.g., Reproduction, Longevity, Morphology, etc.). Figures are permissible to illustrate any data, but should **replace** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send two copies of manuscripts, double-spaced, directly to the section editor.

Standard format for this section is as follows: SCIENTIFIC NAME (in caps), COMMON NAME (lower case, in parentheses) as it appears in Collins (1990. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 3rd ed., Herp. Circ. 19:1-41), KEYWORD (in caps). DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (Name(s) in caps, and address(es) in full). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to a recent issue for citation format).

ANURA

RANA CATESBEIANA (Bullfrog). **PREDATION**. Although Tester (1932. Univ. Toronto Stud. Ser. 36. Pub. Ontario Fish Res. Lab. 46:171-203) includes tadpoles in the normal diet of the smallmouth bass, *Micropterus dolomieu*, little is known of bass predation behavior on tadpoles.

On 25 May 1986 a concentrated aggregation of about 50 *Rana catesbeiana* tadpoles was noticed in ca. 30 mm of water at Ward Lake, Pontiac Z.E.C., Pontiac Co., Quebec, Canada. The site was located on the NW side of a sandy peninsula at the NE end of the lake. The air temperature was 33°C, and there was no cloud cover. To either side of this tadpole cluster were large rocks which formed natural barriers. Aquatic vegetation or other suitable cover was absent. One large tadpole darted away from the group towards deeper water. Upon reaching 300-350 mm of water, the tadpole was consumed by a *M. dolomieu*. Further investigation

revealed that two bass were in the immediate area. Both fish were about 300 mm total length. This behavior was observed for 15 minutes, and three more tadpoles were taken by the fish.

It is unknown whether or not the smallmouth bass played a role in forming the aggregation of tadpoles. No other aggregations were seen. Fourteen *R. catesbeiana* tadpoles were collected and deposited in the herpetology section of the Canadian Museum of Nature (NMC 28490).

Submitted by **RAYMOND A. SAUMURE**, 169 D'Auvergne Ave, Gatineau, Quebec, J8T 1J5, Canada.

RANA CLAMITANS (Green Frog). **ALBINISM**. On 6 June 1991, an albino *Rana clamitans* tadpole was collected (Canadian Museum of Nature NMC 33885) on the Kazabazua River, Pontiac County, Quebec. The tadpole was collected in an inlet of a meandering river. Aquatic vegetation consisted of a few scattered clumps of tape grass, *Vallisneria*. Substrate consisted of a sand and gravel mixture with heavy siltation. A normally pigmented specimen of similar developmental stage was also collected at the site. Green frogs are the most common frog along the river. During eight years of observations at this site, no other abnormally pigmented tadpoles have been observed. Only one other report of albinism in this species has been located (Dyrkacz 1981. SSAR Herp. Circ. 11, 31 pp.).

Submitted by **RAYM0ND A. SAUMURE**, 169 D'Auvergne Ave, Gatineau, Quebec, J8T 1J5, Canada.

TESTUDINES

APALONE FEROX (Florida Softshell). **REPRODUCTION**. Iverson (1985. Florida Sci. 48(1):41-44) reported the range for single clutch size in *Apalone ferox* as 9-24 eggs. In this note we report an unusually large single clutch size and unique nest site.

An *A. ferox* nest containing 32 eggs was discovered on 8 May 1991 in the apron of a recently abandoned *Gopherus polyphemus* burrow located at Boyd Hill Nature Park, St. Petersburg, Pinellas Co., Florida. The nearest body of water (0.186 ha) was located 103 m north. The intervening habitat is classified as scrubby flatwoods (Myers and Ewel 1990. Ecosystems of Florida. Univ. Central Florida Press, Orlando, 765 pp.). The center of the nest was located 71 cm from the burrow mouth. The egg chamber measured approximately 9 cm diam and 14 cm deep.

Sixteen of the eggs were collected, measured (to the nearest 0.5 mm using metric dial calipers), and incubated in sand collected from the nest site at outdoor ambient temperature. Egg diameter measurements on 8 May 1991 were 27.0–33.5 mm ($\bar{x}$ = 29.4 mm, N = 16)

Hatchlings began emerging on 26 July 1991. Twelve emerged at 79 days and one at 80 days post-discovery (81.25% hatch success rate). On 28 July 1991 hatchling carapace length (measured to the nearest 0.1 mm using metric dial calipers) was 36.2–44.3 mm ($\bar{x}$ = 41.2 mm, N = 13), carapace width at mid-point was 29.1–36.4 mm ($\bar{x}$ = 34.2 mm, N = 13), and mass (measured to the nearest 0.1 g using a triple beam balance) was 8.4–11.0 g ($\bar{x}$ = 9.7 g, N = 13).

The *G. polyphemus* burrow system, including its excavated sand mound, provides important habitat for a large number of vertebrates and invertebrates (Campbell and Christman 1982. *In* N. J. Scott, Jr. (ed.), Herpetological Communities. USFWS Wildl. Res. Rpt. 13, pp. 163-171; Jackson and Milstrey 1989. *In* J. Diemer et al. (eds.), Gopher Tortoise Relocation Symposium Proceedings. Florida Game and Freshwater Fish Commission Nongame Wildl. Prog. Tech. Rpt. No. 5, pp. 86-98). In addition, the excavated sand mound serves as an open site for seedling establishment (Laessle 1942. Univ. Florida Publ. Biol. Sci. Ser. 4(1):1-143).

Although *G. polyphemus* generally construct their nests in the excavated sand mound (Iverson 1980. Am. Midl. Nat. 103(2):353-359), this note documents another chelonian species utilizing this site for nesting and reiterates the importance of the burrow apron.

We thank P. A. Meylan for comments that greatly improved an early draft of this note and the staff and volunteers of Boyd Hill Nature Park for assistance during ongoing research.

Submitted by **GEORGE HEINRICH**, P.O. Box 61301, St. Petersburg, Florida 33784-1301, USA, and **DIANE E. RICHARDSON**, Boyd Hill Nature Park, 1101 Country Club Way South, St. Petersburg, Florida 33705, USA.

KINOSTERNON FLAVESCENS (Yellow Mud Turtle). **MULTIPLE NESTING**. Dividing a clutch of eggs into two or more nests is a strategy that has been documented for very few turtle species. The Malaysian river terrapin, *Batagur baska*, divides its clutch of eggs between two or more nests (Moll 1980. Malays. J. Sci. 6:23-62). Fitch and Plummer (1975. Isr. J. Zool. 24:28-42) attributed the discrepancy between small nest complements and large oviductal complements of eggs in smooth softshell turtles (*Apalone mutica*) to division of some clutches between two or more nests.

During a 1992 radiotelemetry study of a population of *K. flavescens* in Henry Co., Illinois, two females divided clutches of eggs between two nests. One female laid two eggs in a nest on 21 June and two eggs in another 3 m away on 22 June. A second female laid 3–4 eggs in one nest on 25 June and about 2 eggs in another nest 2 m away on 26 June. Both nests were destroyed by foxes soon after deposition. Johnson (1987. The Amphibians and Reptiles of Missouri. Conservation Commission of the State of Missouri, Jefferson City, 368 pp.) reported that clutch sizes of *K. flavescens* ranged from 2–6 eggs. This estimate may be low if clutch division is a common behavior of this species.

Predation is a common source of nest mortality for turtles. Multiple nesting is a strategy which may increase nest survivorship by spreading the risk of total clutch failure to predation.

LEPIDOCHELYS KEMPII (Kemp's Ridley Sea Turtle) and ***CARETTA CARETTA*** (Loggerhead Sea Turtle). **DIET**. Juvenile Kemp's ridley (*Lepidochelys kempii*) and loggerhead (*Caretta caretta*) sea turtles seasonally utilize Long Island Sound and the estuarine embayments of eastern Long Island, New York as feeding grounds (Burke et al. 1991. Copeia 1991:1136-1138; Morreale et al. 1992. J. Herpetol. 26:301-308). Piscivory is not commonly reported for sea turtles. Additionally, we have located only one documented case of a seahorse consumed by a sea turtle. A loggerhead stranded in Nova Scotia had a single seahorse (*Hippocampus hudsonius* = *H. erectus*) among numerous food items contained within the gut (Bleakney 1967. Can. Field Nat. 81:269-272). Since 1985 we have examined the dietary components of many sea turtles from Long Island. Here we report three Long Island turtles, two Kemp's ridleys and one loggerhead, that consumed seahorses. Seahorses in all samples represented *H. erectus*. The intestinal tract of the

Kemp's ridley sampled in 1985 contained mostly seahorses (70% by volume, Table 1). The 1990 Kemp's ridley sample and the loggerhead sample contained a smaller proportion of seahorses (20% and 11% by volume, respectively). Notably, the 1990 Kemp's ridley and the loggerhead samples also contained small amounts of floatable plastics.

Hippocampus erectus is the most common seahorse in Long Island waters and is associated with local eel grass (*Zostera marina*) communities. The presence of eel grass and benthic invertebrates in the samples suggest that the three turtles were feeding in eel grass beds. Most seahorses from the 1985 sample had transverse bite marks across their abdomens. These marks, and the minor amount of eel grass in the sample, suggest that the 1985 Kemp's ridley did not incidentally ingest the seahorses.

TABLE 1. Intestinal contents of three sea turtles from Long Island, New York. SCL indicates straight-line carapace length in cm. The number of sea horses consumed is shown in parentheses.

Species	Capture Date	SCL	Diet Item
L. kempii	1 Aug 1985	23.5	*Hippocampus erectus* (20) Small hydrozoans Eel grass (*Zostera marina*)
L. kempii	4 Oct 1990	25.7	*Hippocampus erectus* (3) Small hydrozoans Crab parts (*Cancer irroratus*) Eel grass (*Zostera marina*) Small clear plastic strip
C. caretta	21 Aug 1989	53.3	*Hippocampus erectus* (18) Algae (*Fucus* sp.) Crab parts (*Cancer irroratus*) Small hydrozoans Small mussels (*Mytilus* sp.) Eel grass (*Zostera marina*) Plastics: clear sheet, nylon cord, drinking straw, and multifilament line

Unlike many other fish, seahorses are incapable of rapidly fleeing from predators and depend mainly on crypsis to escape predation (Blake 1980. Can. J. Zool. 58:2116-2119). Once detected, seahorses may be easy for turtles to capture. Young sea turtles may opportunistically exploit seahorses when encountered. Both Kemp's ridleys and loggerheads are known to consume a variety of prey. Observations of seahorses in the diet further emphasizes the degree to which loggerheads and Kemp's ridleys are polyphagous.

We thank Tracy Jones of the University of Georgia Museum of Natural History and Karsten Hartel of the Museum of Comparative Zoology at Harvard University for identifying the seahorses. We acknowledge the assistance of P. Logan, S. Sadove, H. Berna, and K. Roe. Funding was provided by the New York State Department of Environmental Conservation's Return a Gift to Wildlife Program. Manuscript preparation was aided by contract DE-AC09-76SR00819 between the U. S. Department of Energy and the University of Georgia's Savannah River Ecology Laboratory.

RHINOCLEMMYS AREOLATA (Furrowed Wood Turtle). DIET. Specific information on the diet or foraging behavior of *Rhinoclemmys areolata* is not available. Congeners are herbivorous, consuming ferns, shrubs, various seedlings, and occasionally fruit (Ernst and Barbour. 1989. Turtles of the World. Smithsonian Institution Press, Washington, D. C., 313 pp.). I examined the feces of two *R. areolata* collected during the summer of 1992 in order to determine diet. The turtles were collected from a 1000 ha intensively grazed cattle pasture on Gold Button Ranch, Orange Walk District, Belize. The pasture was reverting to an early second-growth forest. Pasture vegetation included various grasses (Poaceae), *Cercropia* spp., and *Acacia* spp.

On 23 June 1992, an adult female *R. areolata* (carapace length = 17.7 cm, weight = 800 g.) was found with head submerged, foraging in a rain-filled depression. It appeared to be excavating flooded leaf litter. The following day the turtle was placed in cool (ca. 25°C) tap water to stimulate defecation. Fecal material contained a large amount of grass, small stones, chitinous remains of unidentified insects, and a large number of eggshell fragments. These fragments may have been from neotropical slider (*Trachemys scripta venusta*) eggs. Sliders were abundant in a nearby (ca. 100 m) man-made lake. More than 75 slider nests along the lake shore had been destroyed by raccoons (*Procyon lotor*). It is not known if the *R. areolata* consumed the slider eggs after excavating the nests or by feeding on eggs from previously opened nests.

On 20 July 1992, another female (carapace length = 13.8 cm, weight = 450 g) was collected from the same pasture. The procedure previously described was employed to stimulate defecation the following day. The fecal material contained numerous elytra from unidentified beetles (Coleoptera) and a large amount of unidentified fibrous vegetation and pieces of fruit, probably *Cercropia* spp. These observations suggest that the diet of *R. areolata* is not strictly herbivorous and that these turtles may consume a variety of animal prey .

TRACHEMYS GAIGEAE (Big Bend Slider). **MAXIMUM SIZE.** Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.) reported the maximum size of *Trachemys gaigeae* as 222 mm (straight-line carapace length; CL). Smith and Smith (1979. Synopsis of the Herpetofauna of Mexico, VI. John Johnson, North Bennington, Vermont, 1044 pp.) reported a maximum CL of "at least 222 mm in females, 166 mm in males." On 27 June 1991, a female with a CL of 257 mm was trapped by JNS from a swiftly-flowing, cold-water reach of the Rio Grande, 1.6 km N of Las Palomas, Sierra County, New Mexico. The collecting site is between Elephant Butte Dam and the upper end of Caballo Reservoir. On 30 June 1992, an intact shell with a CL of

259 mm was collected at the same locality. No extensive melanism was evident in either turtle. Both are preserved in the Museum of Southwestern Biology, University of New Mexico (MSB 51979 and 54750).

A series of 22 adult *T. gaigeae* trapped on 29 June 1990 by two of us (CWP, BCS) at the north end of Elephant Butte Reservoir, Sierra County, New Mexico, included a number of noteworthy specimens. The CL ranges for the series were: females (N = 10), 181-248 mm, $\bar{x}$ = 214.4; males (N = 12), 119-199 mm, $\bar{x}$ = 149.7. The lengths of the four largest females were 248, 244, 231, and 225 mm, and those of the three largest males were 199, 175, and 168 mm. All turtles in this series were marked and released for future studies.

Our data indicate that *T. gaigeae* regularly attains a greater size than has been reported, at least in the northern part of its range (south-central New Mexico). We thank R. D. Jennings, A. J. Landwer, J. S. Ramsey, N. J. Scott, Jr., and P. A. Stone for comments.

LACERTILIA

MESASPIS MONTICOLA (NCN). **REPRODUCTION**. The anguid lizard *Mesaspis monticola* occurs at high elevations in southern Central America. Vial and Stewart (1985. Herpetologica 41:51-57) reported that a 69 mm *Barisia* (*Mesaspis*) *monticola* gave birth to 10 young ($\bar{x}$ = 25.9 mm SVL). Fitch (1970. Univ. Kansas Mus. Nat. Hist. Misc. Pub. 52, 247 pp.) found 3-10 ($\bar{x}$ = 5.35) maturing eggs and embryos in a series of 17 females. No other reports on reproduction by this species are available.

Gravid *M. monticola* were collected from Cerro de la Muerte, Cartago Province, Costa Rica between 2860 and 3250 m elevation on 7 and 8 October 1988 (Table 1). Animals were maintained in a temperature controlled room at 15.5 ± 0.5°C, with light and heat from a heat lamp (28°C) on a 13:11 on:off cycle until 9 December. During this time, these lizards were used in part of a study on anguid behavior. After 9 December they were held at 32 ± 1°C daytime temperature and 22 ± 1°C overnight. Water was available at all times and chambers were misted with water daily. All animals were held separately while in captivity.

Five litters were born in the laboratory from 12 January to 1 February 1989 (Table 2). Body mass was recorded on live specimens, and length was recorded on preserved specimens. Relative clutch mass (RCM), the ratio of total litter mass to female mass (postpartum), was calculated (Table 1).

Fitch (1973. Univ. Kansas Sci. Bull. 50:39-126) suggested a 7–10 week gestation period for this species, with births concentrated in October and November. Vial and Stewart (1985. Herpetologica 41:51-57), however, found that the gestation period is prolonged, lasting about one year, and suggested seasonal synchrony in parturition, occurring in May and June. Births reported here occurred approximately 14.5 and 17.5 weeks after collection; animals were not visibly gravid when collected. Vial (1975. Brit. J. Herpetol. 5:491-495) reported substrate and air (parentheses) temperatures of 9.2°C (8.2°C) minimum daytime and 39.0°C (37.2°C) maximum daytime, and nighttime minimum 3.4°C, at similar (2780–3210 m) elevations in the Cerro de la Muerte, and found the thermal active range of this species to be at body temperatures of 20.2–27.2°C. Laboratory minimum temperatures here were high compared to minimum field temperatures throughout the captivity period, and the increase in laboratory temperature after 9 December resulted in holding the animals within their thermal active range at all times. These factors may have accelerated parturition. It is interesting to note that three of the five litters were delivered on the same day, and the remaining two were delivered within 24 h of one another (Table 1).

TABLE 1. Adult size and reproductive data of *Mesaspis monticola* from Cerro de la Muerte.

	SVL (mm)	Mass (g)				RCM

* Date of parturition.

TABLE 2. Litter and neonate sizes.

Litter	Litter Size	$\bar{x}$ SVL (SD) (mm)	$\bar{x}$ TL (SD)* (mm)	$\bar{x}$ mass (SD) (g)
L-M2	6	24.58 (0.38)	51.85 (0.49)	0.324 (0.005)
L-M10	5	23.85 (0.80)	50.83 (2.86)	0.262 (0.026)
L-M12	2	25.65 (0.14)	54.98 (0.59)	0.342 (0.003)
L-M6	4	25.33 (0.32)	52.71 (1.83)	0.301 (0.013)
L-M7	7	25.91 (0.66)	55.55 (2.16)	0.350 (0.024)

* A tail tip was lost during preservation from one neonate in each of L-M2 and L-M10. Total lengths of these individuals were not included.

Adult *M. monticola* are sexually dimorphic in color pattern, but adult females do not differ significantly from juveniles in nine color characters (Vial and Stewart 1989. Can J. Zool. 67:68-72). Coloration of the adults varied among individuals; coloration of the neonates described herein was similar to that of the known (female) parent.

Seven other adults (3 females and 4 males) were collected along with the five adult females discussed above (Table 1). Two females (M1 and M4) were carrying 6 and 10 enlarged eggs, respectively, in the ovaries at preservation (10 March 1989).

I thank an anonymous reviewer for comments, and E. D. Brodie, Jr. and J. A. Campbell for specimen collection. Collecting permits were issued by Ministerio de Agricultura y Ganaderia, Costa Rica. Specimens were deposited into The University of Texas at Arlington Collection of Vertebrates (UTACV R-26999–27034).

Submitted by **JILL A. WICKNICK**, Department of Biology, University of Southwestern Louisiana, P.O. Box 42451, Lafayette, Louisiana 70504-2451, USA.

SERPENTES

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). **BEHAVIOR.** Cooperative behavior is unusual among ophidians. A series of behaviors involving cottonmouths was observed between 1300 and 1430 h on 28 April 1991 at the University of Mississippi Biological Field Station (ca. 6 air miles NE Oxford, Lafayette County, Mississippi). The station has numerous spring-fed ponds within a valley surrounded by forested hills. The day was windy with an overcast sky. Air temperature was 21°C at 1330 h.

While walking a grassy levee between rows of small (<1000 m^2), shallow (<0.5 m depth) ponds, I observed 4 adult cottonnouths near a pond discharge pipe. Recent heavy rains had produced a strong outflow of water from the pipe that formed a small pool at the western end of a nearly empty pond. The pool was about 1 m^2 in surface area and about 25 cm deep. A shallow rivulet emerged from the pool, meandered about 7 m across the mudflat, and collected at the deeper, eastern end of the pond.

The cottonmouths had their heads and necks elevated and were alertly facing the pool. None was distracted by my approach to within 3 m. During five minutes of observation, the snakes remained alert and motionless. I then left the area.

When I returned about 30 min later, three cottonmouths were still facing the small pool below the outflow pipe. The fourth was in the rivulet at the pool's edge and swallowing a small sunfish (*Lepomis* sp.). The current soon swept the snake downstream. One of the three remaining snakes then moved into the pool. Immediately, several small sunfish (<8 cm) leaped from the pool, landing near the two cottonmouths on shore. Both quickly attempted to capture the fish, but the fish returned to the pool. More small fish leaped from the pool (apparently escaping from the submerged cottonmouth). One landed on a snake! The two snakes repeatedly and unsuccessfully attempted to capture the flopping fish. Within the next minute, three more fish junped onto land. One snake finally captured a fish. The unsuccessful cottonmouth then moved into the pool. More fish immediately leaped from the pool onto land. I then left the site.

I returned briefly about 15 min later. Two cottonmouths were again on land and alertly facing the pool. The cottonmouth that had drifted downstream was rejoining them. The fourth was not evident.

While these behavioral patterns are not cooperation in the strictest sense, the snakes on land were taking advantage of the fish-disturbing activities of an individual in the pool. Body postures and actions suggest individual alertness, perhaps even anticipation, to the possibility of aquatic prey appearing on land. Chance profiteering from opportunistic behaviors such as these may have had an important selective role in the evolution of cooperation.

ALSOPHIS PORTORICENSIS RICHARDI (Ground Snake). **FEEDING.** *Alsophis portoricensis richardi* is an opisthomegadont colubrid snake which can use a highly variable toxic secretion to subdue live prey. The feeding habits of this colubrid are poorly known among the islands of the eastern Puerto Rican Platform, but anolid and sphaerodactylid lizards are presumed to be primary prey in the Virgin Islands (MacLean 1982. Reptiles and Amphibians of the Virgin Islands. Macmillan Caribbean Education, Ltd., London; see also Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville, 720 pp.). Here I give two accounts of previously unreported and unusual prey items and feeding behavior for *A. p. richardi* observed at two small cays; Congo Cay located 2.5 km NW of Cruz Bay, St. John, 18°22'N, 64°46'W and Little Saba Cay 5 km S of St. Thomas, 18°19'N, 65°00'W.

On Congo Cay, an *A. p. richardi* was masticating dried fish below a seabird nest. The snake, about a meter in length, appeared to search deliberately among the slab-like rocks to collect in its jaws small, dried fish, *Herangula* sp., approximately 2-3 cm in total length. The dessicated and hard fish, originally food for brown pelican nestlings (*Pelecanus occidentalis*), had been lost over the side of the nest three meters above ground level. At Little Saba Cay, I observed a large *A. p. richardi* entering a nest containing two eggs of a ground-nesting bird, Zenaida dove (*Zenaida aurita*). The snake was positioning its head over the eggs while the adult dove was standing nearby flicking its wings in a combative posture when my presence disturbed the snake. In both cases, the prey was immobile, desiccated, or hard.

I thank the staff of the Division of Fish and Wildlife, St. Thomas, USVI, for field assistance; James Lazell, Jr., Greg Mayer, and Peter Tolson for their encouragement; and Stephen Corn for critical review of earlier drafts of the ms. Field work was made possible by the Pittman-Robertson Virgin Islands Wildlife Restoration Aid Program (FW-3), U.S. Fish and Wildlife Service, Atlanta, Georgia.

CLONOPHIS KIRTLANDI (Kirtland's Snake). **DIET.** Worms and slugs have commonly been reported as major food items for this secretive snake (Conant 1938. Amer. Midl. Nat. 20:1-200; Minton 1972. Amphibians and Reptiles of Indiana. Indiana Acad. Sci. 346 pp.; Pope 1944. Amphibians and Reptiles of the Chicago Area. Chicago Nat. Hist. Mus., 275 pp.). Parmalee (1955. Reptiles of Illinois. Illinois St. Mus., 88 pp.) stated they also eat small fish and amphibians, and Barbour (1971. Amphibians and Reptiles of Kentucky. Univ. Press of Kentucky, Lexington, 334 pp.) mentions

all of these, plus "insects." One rainy night on 13 October 1985 I ran over a *Clonophis* on the road below the Mississippi bluffs in extreme southwestern Adams Co., Illinois. It disgorged a water strider (*Gerris* sp.). I had never previously seen any animal prey on this common aquatic insect, though presumably it has other predators. This *Clonophis* and two others from Illinois (WIU 14138-14140) were later dissected, but their digestive tracts were devoid of recognizable items.

Submitted by **GORDON R. THUROW**, Department of Biological Sciences, Western Illinois University, Macomb, Illinois 61455, USA.

CROTALUS WILLARDI WILLARDI (Arizona Ridgenose Rattlesnake) and ***CROTALUS LEPIDUS KLAUBERI*** (Banded Rock Rattlesnake). **ARBOREAL BEHAVIOR**. Although crotalines are not commonly encountered in trees and bushes, they have been observed to climb into them occasionally (Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. 2nd ed., Univ. California Press, Berkeley, 1533 pp.). We observed climbing behavior on two occasions in the Huachuca Mountains in southeastern Arizona.

On 9 September 1992 at 0930 h, a subadult *C. w. willardi* was observed draped in a poison oak bush (*Toxicodendron diversilobum*) ca. 46 cm above ground. The air temperature was ca. 22°C. On the same date, at 0945 h, a juvenile *C. l. klauberi* was observed ca. 61 cm above ground wedged between the ridges in the bark of a large Ponderosa pine (*Pinus ponderosa*).

Hypotheses explaining why rattlesnakes climb include thermoregulation (basking), escape from high water, and foraging behavior. The *C. w. willardi* may have been basking as it was in filtered sunlight. However, the *C. l. klauberi* was in complete shade. Alternatively, rattlesnakes may climb to avoid predators. Large numbers of coatimundis (*Nasua nasua*) were seen in the area recently, and the ground near the snakes was disturbed.

Submitted by **JOHN V. ROSSI**, Blanding Animal Hospital, 5610 Blanding Blvd., Jacksonville, Florida 32244, USA, and **JERROLD J. FELDNER**, Southwestern Herpetologists Society, P.O. Box 7469, Van Nuys, California 91409, USA.

HETERODON PLATIRHINOS (Eastern Hognose Snake). **MELANISM HEREDITY**. Do eastern hognose snakes ever hatch black? Michener and Lazell (1989. J. Herpetol. 23:35-40) recognized two sorts of black hognose snakes: "slate" and "satin." They suggested slate was the extreme of variation in a continuum of gray pigmented individuals, but that satin was a discrete morph. Alternately, there may be an ontogenetic shift to black in some eastern hognose snakes (William Palmer and Alvin Braswell, North Carolina State Museum, Raleigh; pers. comm.), similar to that in some racers (*Coluber constrictor*) and some rat snakes (*Elaphe obsoleta*). Only the grayest hognose snake hatchlings, those without red pigments (pink, russett, or orange), would make the shift.

A satin black female 708 mm total length (TL), captured at Moncure, Chatham County, North Carolina, laid seven eggs 10 July 1992. These hatched 6 September 1992. The litter included three males 192–204 ($\bar{x}$ = 200) mm TL, with tails 19–20 ($\bar{x}$ = 19.6) percent of TL, and four females 192–207 ($\bar{x}$ = 202) mm TL, with tails 16–17 ($\bar{x}$ = 16.3) percent of TL. All had some red nape coloration (at least), appeared normally pigmented, and were boldly patterned with 20–24 ($\bar{x}$ = 22; no sexual difference) body saddles. Males had 9.5–12 ($\bar{x}$ = 10.3) tail bands. Females had 8.5–9 ($\bar{x}$ = 8.9) tail bands. Nape ground color varied from coral-orange through rose and terra cotta to pinkish-gray. Posterior ground colors were terra cotta, pinkish-gray, lavender-gray, various shades of gray-brown, and ash-gray. Elucidation of heredity will involve rearing hognose snakes of known black parentage, so as to determine onset and duration of phenotypic shift, and backcrossing them to at least one parent. The first hypothesis to attempt to reject is that eastern hognose snakes never hatch black.

FIG. 1. A satin black eastern hognose snake and her normally pigmented litter of seven. Photo by Vann Covington.

I am indebted to Vann Covington, Department of Entomology, North Carolina State University, Raleigh, for permission to examine and report on the snakes captive in his care, and for Figure 1. This Agency's work in North Carolina and the Southeast is supported by The Grace Jones Richardson Trust.

GEOGRAPHIC DISTRIBUTION

New County Records Of Amphibians And Reptiles From West-Central Texas

From May of 1987 to July of 1992, while conducting field surveys and monitoring populations of the Concho water snake (*Nerodia harteri paucimaculata*), numerous new county records were documented. Voucher specimens for these were deposited in the Texas Cooperative Wildlife Collection (TCWC) at Texas A&M University, and are reported herein. Dixon (1987, Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas, 434 pp.) updated the distribution maps for all Texas species of amphibians and reptiles. Additional county records have subsequently been reported for this region of the state (McAllister et al. 1987, Southwest. Nat. 32(3):406–408; Gannon 1987, Texas J. Sci. 39(3):293; Schafer and Kasper 1989, ibid 41(3):337–338; Cordes et al. 1990, ibid 18(2):209–210; Bridegam and Smith 1987, Herpetol. Rev. 18(2):40; Calaway et al. 1988, ibid 19(1):19; Cordes et al. 1987, ibid 18(2):40; McAllister et al. 1987, ibid 18(1):20; McAllister et al.

1986, ibid 17(4):92; McCord and Dorcas 1989, ibid 20(4):94,96; Butterfield et al. 1991, ibid 22(1):28; Hibbits 1991, ibid 22(2):65; and Hibbits 1991, ibid 22(2):68.).

In this note we list 37 new county records for west-central Texas and fill distributional gaps for 28 species of reptiles and amphibians (Dixon 1987, op. cit.). These specimens were collected by the authors and various other field personnel who have worked on the Concho water snake project during the past five years. Some of these new records were incidental collections made by the senior author prior to May 1987. Verification of specimen identifications was by James R. Dixon. Standard common names are from Collins (1990 SSAR Herp. Circ. 19:1–41).

ANURA

Scaphiopus bombifrons (Plains Spadefoot). Callahan Co: 1.6 km E Clyde. 11 May 1981. TCWC 67506.

Acris crepitans crepitans (Northern Cricket Frog). Titus Co: Horse Creek, 0.8 km S IH 30. 14 October 1991. TCWC 69250, 69251.

Pseudacris streckeri streckeri (Strecker's Chorus Frog). Callahan Co: 1.6 km E Clyde. 4 February 1987. TCWC 69056; Coleman Co: North Prong of Hords Creek, 7.2 km NW Glen Cove. 1 June 1987. TCWC 69057.

Bufo debilis debilis (Eastern Green Toad). Concho Co: Kickapoo Creek, 8.1 km SW Paint Rock. 27 May 1987. TCWC 68095, 68096; Runnels Co: Ballinger Municipal Lake spillway. 30 June 1987. TCWC 67854.

Bufo speciosus (Texas Toad). Runnels Co: Elm Creek, 6.3 km N Ballinger. 29 June 1987. TCWC 67868.

Bufo valliceps valliceps (Gulf Coast Toad). Runnels Co: Colorado River, 14.8 km WSW Ballinger. 21 September 1988. TCWC 67346.

TESTUDINES

Apalone spinifera guadalupensis (Guadalupe Spiny Softshell). McCulloch Co: Cow Creek, 5.6 km E Lohn. 1 June 1987. TCWC 66103; Lampasas Co: Little Lucy Creek at low water crossing, 9.3 km NNE Lampasas. 13 July 1987. TCWC 66101; Mills Co: Colorado River, 3.2 km W Oakland Church, jct FM 586 & SH 45. 21 June 1988. TCWC 68469.

Chelydra serpentina serpentina (Common Snapping Turtle). Runnels Co: Lake Winters spillway, 8.9 km E Winters. 30 June 1987. TCWC 69095; Irion Co: Spring Creek at FM 915, 4.3 km SSW Mertzon. 14 May 1991. TCWC 69094; Coleman Co: 0.8 km S Whon. 27 August 1991. TCWC 69713.

Pseudemys texana (Texas River Cooter). Irion Co: Middle Concho River, 9.7 km W SH 163. 1 July 1987. TCWC 65386; Coleman Co: Elm Creek, 4.8 km NNE Freese Dam (formerly Stacy Dam Site). 26 July 1987. TCWC 65906.

Kinosternon flavescens flavescens (Yellow Mud Turtle). Lampasas Co: 13.4 km NW Adamsville. 14 July 1987. TCWC 66111.

Kinosternon (Sternotherus) odoratus (Common Musk Turtle). Concho Co: Concho River at Vinson Dam, 5.8 km W Paint Rock. 20 July 1987. TCWC 69701; Coleman Co: Home Creek, 8.9 km SW Santa Anna. 10 July 1992. TCWC 69913.

Trachemys scripta elegans (Red-eared Slider). Irion Co: Spring Creek at Mertzon City Park low water crossing. 16 May 1991. TCWC 68657.

Terrapene ornata ornata (Ornate Box Turtle). Schackleford Co: 24.9 km WNW Albany on Rt. 180. 23 May 1992. TCWC 69898.

SAURIA

Eumeces obsoletus (Great Plains Skink). USA: TEXAS: Taylor Co: 0.5 km W SH 351 on IH 20. 10 June 1982. TCWC 67743.

SERPENTES

Lampropeltis getula splendida (Desert Kingsnake). Glasscock Co: 4.5 km W Garden City on SH 158. 23 June 1979. TCWC 66038.

Lampropeltis calligaster calligaster (Prairie Kingsnake). Callahan Co: unnamed county road 0.8 km W FM 604, 1.6 km N of IH 20. 28 November 1982. TCWC 66045.

Regina grahamii (Graham's Crayfish Snake). Coleman Co: Bull Creek, 0.5 km E Gouldbusk on FR 1026. 19 May 1987. TCWC 66028; Tom Green Co: Concho River at FM 1692, 6.4 km S Miles. 19 July 1988. TCWC 67237.

Virginia striatula (Rough Earth Snake). Coleman Co: 1.0 km NNE Freese Dam (Stacy Dam). 24 May 1987. TCWC 66020.

Heterodon nasicus (Western Hognose Snake). Coleman Co: Freese Dam (Stacy Dam). 26 May 1987. TCWC 66046.

Opheodrys aestivus (Rough Green Snake). Coleman Co: 0.5 km S Leaday. 26 May 1987. TCWC 66049.

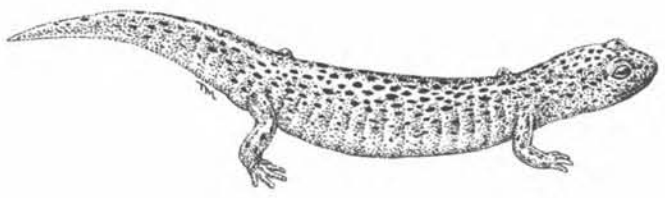
Hypsiglena torquata jani (Texas Night Snake). Irion Co: 5.8 km S Mertzon. 9 June 1987. TCWC 66018.

Nerodia rhombifer rhombifer (Diamondback Water Snake). Irion Co: Middle Concho River, 21.7 km NW Mertzon. 1 July 1987. TCWC 67630.

Nerodia erythrogaster transversa (Blotched Water Snake). Callahan Co: Pecan Bayou, 16.1 km ESE Oplin above confluence of Crooked Creek. 8 June 1992. TCWC 69899.

Masticophis taeniatus schotti (Schott's Whipsnake). Lampasas Co: Lynch Creek at FR 580, 10.8 km SW Lometa. 8 July 1987. TCWC 68944.

Sonora semiannulata (Ground Snake). Jones Co: Deadman Creek, 10.0 km SSE Leuders. 23 May 1992. TCWC 69900.



Storeria dekayi texana (Texas Brown Snake). Runnels Co: Colorado River at Egan Dam, 8.5 km NNW Rowena. 5 September 1991. TCWC 69253.

Gyalopion canum (Western Hooknose Snake). Concho Co: O. H. Ivie Reservoir, Hafner Island, 3.5 km N SW end of Freese Dam. 6 April 1992. TCWC 69688.

Sistrurus catenatus tergeminus (Western Massasauga). Jones Co: 11.6 km SSE Leuders. 23 May 1992. TCWC 69901.

Acknowledgments.—We are indebted to Jimmy Folkner, John Page, Jr., Freddie Grohman, Steve Stone, Steve Beal, and Chuck Brown for their assistance in conducting field surveys. Funding and facilities for this project were provided by Colorado River Municipal Water District (CRMWD), Big Spring, Texas. Collections were made under the authority of the Texas Parks & Wildlife Department Scientific Permit No. SPR–790–208 to CRMWD. James R. Dixon reviewed an earlier version of this note and made useful suggestions.

BOOK REVIEWS

The Reproductive Husbandry of Pythons and Boas, by Richard A. Ross and Gerald Marzec. 1990. Privately published by the Institute for Herpetological Research (P.O. Box 2227, Stanford, California 94305, USA). 270 pp, 249 color photographs, 11 black and white photographs, 11 text figs., 52 reproductive graphs. $75.00 U.S. (hardcover).

This book is a larger, more comprehensive, and much more colorful version of Ross' *Python Breeding Manual* (1978), that compiled much of the early data on the subject. In the dozen intervening years, interest in reptile husbandry has grown enormously, motivated by declining wild populations and the concomitant escalation of commercial prices for good broodstock. Reptile breeding has become very commercial, requiring sophisticated techniques and high technology equipment. Ross and Marzec are prominent figures in boid husbandry and their book summarizes many of the recent advances in the field.

The book is divided into two sections, the first consisting of six chapters covering various general aspects of the care and breeding of boids: 1) General Husbandry of Breeding Stock; 2) Reproductive Husbandry; 3) Disorders of Reproduction and Pregnancy; 4) Egg Husbandry and Incubation; 5) Husbandry of Neonate Boids; and 6) Genetics of Boid Reproduction. The final section opens with a short chapter titled "Captive Husbandry and Seasonality." It briefly discusses the absence or existence of breeding seasons in wild populations from temperate and tropical climates, and gives explanatory comments relating to reproductive graphs that illustrate the subsequent species accounts. These are discussed in the final two chapters, the first dealing with reproductive data for pythons and the second for that of boas.

In general the book is well produced and well proofed, with very few typographical errors. The binding is strong and glossy paper is used throughout (although there is a generous amount of blank paper, and placing six empty pages at the front of the book isn't an attention grabber!). Five pages of references, a three-page glossary, an appendix of medication dosages, and nine-page index complete the book. The Literature Cited lists many important works, but is by no means comprehensive even for boid captive breeding and ignores much of the great wealth of foreign literature that exists on the subject.

The layout of the species accounts is geographical rather than systematic, and this leads to some confusion. All sand boas, for instance, are discussed under Madagascar and African boas, even though most *Eryx* (8 of 12 species) are Arabian or Eurasian. They are closely-related to the small North American rosy and rubber boas (and usually placed in a separate subfamily, Erycinae), and yet their husbandry or reproduction is never compared or contrasted with these snakes. In addition, the inclusion of tropidophids and bolyeriids would be questioned by most systematists as they are now usually placed in separate families (Underwood 1976), or even separate superfamilies (McDowell 1979). These small, primitive snakes are so rare and restricted that they are unlikely to be of interest to any but the most specialized collector. They should have been left out.

The species accounts would also have benefited from a few introductory sentences, giving the ranges, habitats, and systematic references for each species. In the Preface the authors note that the "taxonomy of the Boinae is currently in a state of flux." This is very true, given the recent spate of conflicting revisions (e.g., McDowell 1975, 1979; Underwood 1976; Underwood and Stimson 1990), and the authors are probably correct in not adopting a higher classification that might soon have been outdated. However, they could at least direct the interested reader to the relevant literature. They should also have given a brief overview of the classification they adopted, as I doubt that they really consider pythons, boas, and tropidophids as being included in a single subfamily, Boinae. For many species, the lack of basic natural history data inhibits understanding, particularly for herpetoculturists trying to keep a species for the first time. How many people know the distribution of the blood python or on which islands the different races occur? Information on the average size that a species attains at least gives an indication on what size it may be expected to reach at sexual maturity.

The authors have done an admirable job in condensing reproductive data for the different species, and the first section on general husbandry contains a wealth of information for herpetoculturists. However, my biggest disappointment is not for what the book contains, but for what it lacks. That is a lack of excitement for the snakes themselves; for an understanding of their lives in the wild. There is no attempt to overview reproductive strategies within the Boidae, or to find what subtle differences in biology make some groups successful, and others less so.

The reproductive capabilities of snake lineages are not equal, and the biology of any species is constrained by its phylogeny. For example, within *Python*, egg size is relatively constant, and the number of eggs produced intra- and interspecifically is usually a function of body length (Branch and Erasmus 1984). The same relationship between clutch size and body length generally holds throughout the subfamily (although egg size may also get smaller in dwarf species, such as *Liasis childreni*). This is not the case with many boas, in which interspecific variation in the number and size of neonates may vary considerably, even within the same genus, e.g., *Acrantophis* and *Epicrates* (Branch and Erasmus 1984).

So what are the similarities and differences among the various boid lineages? What features of their reproduction are phylogenetically constrained, and what features are specific adaptations to similar habitats? The latter may highlight convergent evolution between different groups, and may identify features more amenable to manipulation in captivity. Ross and Marzec have a wealth of data on reproduction in pythons and boas that may answer such questions within different lineages of these primitive snakes. It is a pity they make no attempt to broach, let alone answer, such questions.

Despite these quibbles (which make me feel a bit like a spoilt boy wanting another cherry on top of his chocolate cake!), this is an excellent book and should do much to stimulate and promote the husbandry and breeding of boids.

Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History, by Albert Schwartz and Robert W. Henderson. 1991. University of Florida Press, Gainesville, ISBN 0-8130-1049-7. xvi + 720 pp. $75.00 U.S. (hardcover).

Having worked in the West Indies for more than twenty years, I always relish the receipt of a new publication by Albert Schwartz. Al's work has always been characterized by an exactness and attention to detail that is satisfying and refreshing. The experiences of more than forty years of field work in the Antilles infuse his publications with a wealth of useful data. The culmination of Al's career has been a series of books on West Indian herpetology co-authored with Bob Henderson. Although several of the earlier contributions were uncharacteristically rife with careless errors, the most recent compendium causes no such disappointment. There is much to praise in the volume, beginning with Rose Henderson's spectacular watercolor of a male *Anolis marmoratus* on the dust jacket and frontispiece. This fine illustration is not identified to subspecies, but it is apparently *A. m. marmoratus*, a truly striking lizard. Visitors to Guadeloupe should be forewarned, however, that *A. m. speciosus* from the vicinity of Pointe-a-Pitre is drab by comparison, an indication of the considerable variation within a small area that is so common in the Antilles.

Although tempted to praise the many strong points of this volume, I am sure that other reviewers will adequately extol its virtues. With apologies to Al and Bob, I will try to focus on the flaws, which are admittedly minor and inevitable in a work of this scope, but they are present and occasionally inexplicable. However, book reviews, like baked goods, are best when fresh and the less obvious problems of a book only surface with repeated use. I have not had this luxury, but I am familiar with the fauna and the associated literature. I read through the book completely and flagged areas that did not "look right." I then checked the details in these accounts. I found too many errors for this review to be an effective errata sheet, so I have cited only representative problems, without trying to imply that a high degree of inaccuracy occurs throughout. One assumes, however, that a series of books on the same area would have a winnowing effect, gradually eliminating errors and problems in previous volumes. Distressingly, some of the errors found in this volume were correctly presented earlier.

Tradition dictates that a review should provide some idea of the book format, so my comments are arranged accordingly. The introduction (pp. 1-4) concisely summarizes what is contained in the text of the book and how the information was accumulated. The taxonomy follows the Schwartz and Henderson (1988) checklist, but "with some exceptions" that are neither listed nor explained. One of the most obvious is that the much-disputed generic re-arrangement of *Anolis* by Guyer and Savage (1986) has been abandoned. A brief chronological history of species descriptions documents that significant discoveries are still being made and the authors admirably emphasize that much remains to be done.

The acknowledgments (pp. 5-6) reveal that unpublished field observations from selected individuals were included, but little effort was expended to solicit information from many other potentially rich sources. Years ago it was easy to "touch base" with virtually all other researchers working in the Antilles before publishing, but now a cast of thousands has discovered this interesting area. I am sympathetic to this problem, but the number of major institutions with ongoing Antillean projects is much more manageable. Almost without exception, these sources were available to Schwartz and Henderson but the appropriate staff members were unaware of the imminent appearance of this volume, so important collections and ancillary information were not included. As an example, collections from as long ago as 1985 (SDSNH and USNM) demonstrate that both *Eleutherodactylus johnstonei* and *Gymnophthalmus* sp. are much more widely distributed on Guadeloupe (including Basse Terre) than the maps indicate.

Flowery passages on "the many wonders I have seen" seem *de rigueur* for regional monographs these days but Schwartz and Henderson's "Envoi" section (pp. 14-16) is commendably restrained. The section leads off with a quote by the misguided W. Bancroft Espeut, extolling the virtues of mongoose. It is perhaps appropriate that Espeut's name is misspelled in both the quote and Literature Cited. The role of introduced biota and unwise land-management practices in the extinction process is briefly discussed but it was disappointing that no mention was made of the historical aspects of extinction in the West Indies. There is considerable literature on the role of Amerindians in floral and faunal change of the past few thousand years. The introduction of feral animals and habitat destruction by Europeans may have been the coup de grace for some native species but they were brought to the brink of extinction well before European contact. Without this historical perspective the authors reinforce the misconception that West Indian extinctions are primarily a recent phenomenon that can be blamed on the excesses and indiscretions of modern man.

The species accounts (pp. 19-672) justifiably occupy the bulk of the book and they are well-organized and coherent. They are remarkably free of typographical and technical errors, but a few creep in: on page 181, *Ameiva ameiva fuliginosa* (not *fulginosa*) was described by Cope 1892 (not 1862); Petzold is misspelled Petzhold on p. 408. *Leptodactylus dominicensis* was synonymized with *albilabris* by Heyer (1978); although I do not agree with this taxonomic arrangement, it has never been formally refuted. The distribution maps are indispensably useful but occasionally their placement relative to the species account may be momentarily confusing. Although the species accounts contain a great deal of useful information, I was puzzled by the lack of pertinent information in some accounts. *Ophisaurus ventralis* and *Gonatodes* in the Caymans are included without reference or comment, despite the fact that they were previously unreported either from the island (in the case of *Gonatodes*) or from the entire Antilles (*Ophisaurus*). There is nothing inherently wrong with publishing new information in a checklist, but it should be adequately referenced. In the case of unpublished information, this can be in the form of a "personal communication" from the contributor(s) (as done in the Natural History section) or citation of manuscripts in preparation or in press. In fact, if I have a major complaint about this book, it is the paucity or appropriateness of the references. A true reference

book should not only be referred to *for* information but it should also refer one *to* the original sources of that information. This is particularly notable in the accounts for non-native species, where most of the references are to North American field guides. Admittedly, these are good sources of illustrations, but they offer little (if any) information pertinent to the Antilles. The *Catalogue of American Amphibians and Reptiles* accounts are largely ignored (none is listed in the Literature Cited) and these are valuable summaries of published illustrations and much other information. By citing the *Catalogue* account for the species (if available) the References in this volume could concentrate on the original and any subsequent reports from the Antilles. Even for native Antillean species, the references were variable in their appropriateness. In *Leptodactylus fallax*, for example, no mention or reference was given for the (apparently) unsuccessful introductions of the species on Jamaica and Puerto Rico, or for its historical extinction on St. Kitts, Guadeloupe, and St. Lucia.

The mapped distributions occasionally do not match the text and the extralimital distributions are often incorrect. *Kentropyx borckianus* occurs only on Barbados and in the Guianas, but not on Trinidad, which is inhabited by *K. striatus*. Although there are two isolated records of *Hemidactylus palaichthus* from Trinidad proper (and none from Tobago), the species is generally found on offshore islands (Chacachacare, Little Tobago), as is the case on the Maria Islands off St. Lucia. C. J. Cole and co-authors have demonstrated recently (after Schwartz and Henderson was in press) that virtually all of the *Gymnophthalmus* records for Dominica and Guadeloupe are *underwoodi*, rather than *pleei*, but the presence of both species on Guadeloupe in the Schwartz and Henderson maps should have been suspicious.

The Natural History section of the species accounts is wildly uneven in its accuracy and utility, although I think it is a potentially useful addition. Characterizing a species as a "xerophile," "mesophile," "forest associated," or other encapsulization is always fraught with risk, since species generally defy such facile simplifications. No exception here, and there are numerous cases of xeric species being found in patently mesic situations and vice versa. However, given the relatively limited sources consulted for such information and the constraints of summarizing it in such a small space, I was surprised that this section made as much sense as it did. However, I question that "going in front entrance of cafe" is a particularly salient observation on the natural history of *Gymnophthalmus underwoodi* (p. 412), even though I have found *G. speciosus* doing exactly the same thing in Panama.

In summary, this is a good book and one that few biologists or amateurs can do without. However, if you cannot do without this volume, you will have to invest in many of the previous Schwartz and Henderson volumes as well, since they are inextricably linked and each is considerably less useful without the information in one or more of the others. This may be mere coincidence or a clever marketing ploy, but the final word on the West Indies is not yet in. Many more species await description, and distributions of some species may change drastically with additional data and taxonomic resolution. In a few more years, this volume may well be two or even three volumes. Until then, buy Schwartz and Henderson, save your pennies, and hope that the next edition offers as much information at such a bargain price.

A Water Snake's Year, by Doris Gove, illustrated by Beverly Duncan, 1991. Atheneum Publishers, New York, NY. 40 pp. $13.95 U.S. (softcover).

This is a rather unusual book to be reviewed in a herpetological journal, not due to the subject matter, but rather the intended audience. *A Water Snake's Year* is a children's story, aimed mainly at second to fifth graders (ages 7 - 11 years). It is a story of the life and times of a six-year old female water snake (*Nerodia sipedon*) living near the Middle Prong of the Little River in the Smoky Mountain National Park of east Tennessee.

Over the course of the tale, we follow the snake from her emergence after winter's hibernation through the daily toils of fishing, basking, and staying safe from predators. Our scaly heroine sheds her skin, encounters various other denizens of her home range, mates, and finally gives birth to a litter of babies before returning to her hibernaculum for the next winter. Excitement occurs mid-summer as a rainstorm washes the snake downstream and she must find her way home through unfamiliar territory. I found the guest appearance of a defensively "fluttering" hellbender a nice touch.

This story is a positive and highly accurate depiction of what life may be like for the average (lucky) water snake. Descriptions of snake behavior and natural history are rich and detailed, as one would expect from this author. Doris Gove has conducted research into the evolution of behavior in snakes and lizards, and lives and works in and near the Smoky Mountains.

The book is also visually impressive. The artwork is an important part of the storytelling, and is lush and attractive, with the text flowing aesthetically into the artwork rather than the other way around. Various plants, flowers, and other animals found in the Smokies make their appearances in Beverly Duncan's watercolors. There are often small critters peeking out from under leaves or the water surface that will be fun for children to notice. The accuracy of the drawings is also quite good, though the water snakes are sometimes a bit too long-bodied in proportion. This small error is probably far beyond the ability of the intended readers to criticize, and certainly does not detract from the story or the look of the artwork.

One thing I found amusing about this book was the index. I have never before seen a children's book with an index, and the subjects found there are somewhat intriguing. For instance, you can look up the pages where acorns, inner tubes, or water striders are mentioned. I suppose this would be a good tool for getting kids to use an index; I even had some fun with it.

The only possible drawback of the book as I read it is in the tone of the writing. I wonder if the story, as quiet and unassuming as it is, is exciting enough to capture the attention of the children reading it, particularly in this age of high adventure cartoons, action figures, and interactive computer games. It may have been

nice to have personalized the snake a bit more (at the risk of anthropomorphizing too much) to make the readers care more about her. Perhaps giving her a name, or making her scrapes with danger more thrilling would help.

Overall though, this is an attractive and informative book, describing a snake and its world in a positive light to young readers—a fairly rare undertaking and one I wholly support. I am only familiar with two other children's stories featuring "good" snakes, and both are quite fantastic tales with virtually no realism (*Crictor*: Ungerer 1958; and *Mr. Yowder and the Giant Bull Snake*: Rounds 1978). Of course, Kipling's *The Jungle Book* (1895) portrays Kaa as a wise snake and Mowgli's teacher (unlike the more recent, and probably better-known, Disney-version of the story), though I'm not convinced that Kipling was writing for children. I look forward to giving copies of this book to young nieces, nephews, and friends, some of whose parents may not approve of a more direct introduction to the subject matter of herpetology.

Captive Invertebrates. A Guide to Their Biology and Husbandry, by Fredric L. Frye. 1992. Krieger Publishing Company, Malabar, Florida. 135 pp. $29.50 U.S. (hardcover).

Why should a book on invertebrate husbandry be of interest to herpetologists? Aside from the fact that many herpetologists are nominally the local experts on all "creepy crawlies," there is the very practical issue of insects and other invertebrates as feeder organisms for captive amphibians and reptiles. Most people solve the problems of maintaining live invertebrates through trial and error based on common sense. Nonetheless, there is a clear need for a practical guide concerning the biology and husbandry of these animals; the book by F. L. Frye is an attempt to meet this need. Frye's book begins with an introductory section that contains a convincing discussion on the aesthetics and relevance of invertebrates in our daily lives. The introduction is followed by a separate chapter on special accommodations for terrestrial, arboreal, and aquatic invertebrates. Subsequent chapters deal with the biology and husbandry of specific invertebrate taxa, including arachnids, chilopods and diplopods, insects, crustaceans, pulmonate snails and slugs, and turbellarians. These chapters cover diagnostic characters, housing needs, water requirements, nutrition, reproduction, and medical disorders. While much of this information is simple common sense (e.g., "dry branches or flat stones . . . must be adequately propped or anchored so that they cannot topple over and crush the inhabitants"), other material is quite useful and interesting. Frye does a nice job at keeping the reading lively by including interesting trivia. For example, how many people know that the silk of black widow spiders served as cross hairs in World War II bomb sights and sniper rifle scopesights? The combination of Frye's genuine interest in invertebrates and his training in veterinary medicine provides a unique perspective into how medical disorders can affect laboratory insect cultures. Anyone who has ever maintained invertebrate cultures that occasionally "crash" will especially appreciate Frye's discussions on the effects of bacterial, viral, and protozoan infections on culture vitality.

The last chapter is the one most clearly relevant to herpetology and discusses the culturing of invertebrate prey species as food sources for vertebrates. Taxa covered include earthworms, crickets, mealworms, silkworms, waxworms, fruit flies, and houseflies. Much of this information is already available in the literature of biological supply houses, but is conveniently brought together here. Other things that will make this book useful to both professional and amateur zoologists are an appendix that lists addresses of commercial sources for some living invertebrates, a glossary, an extensive list of suggested readings and comprehensive indices. Although the book is well illustrated, with 96 color plates, these are inconveniently separated from the text in separate sections. Further, the unusually wide text margins (4 inches on 8.5 inch width pages) detract from the design of the book and artificially inflate its size. Of passing interest to most herpetologists, this book may find a place on the shelves of those who maintain their own invertebrate cultures to support large numbers of captive amphibians and reptiles.

PUBLICATIONS RECEIVED

An Introduction to Snakes of the Dismal Swamp Region of North Carolina and Viriginia, by Donald R. Brothers. 1992. 139 pp. Softcover. $10.00 + $2.50 shipping and handling. (Available from Edgewood PROBES, Inc., HC 33, Box 1176, Boise, Idaho 83706, USA).

According to the preface, this book's purpose "is to provide general information for those with an interest in or curiosity about snakes of the Dismal Swamp region and to dispel popular false beliefs about them." Twenty-seven species are illustrated by 32 high quality color illustrations (executed by the author). Numerous black and white drawings depict dorsal, ventral, and lateral aspects of each species. Distribution maps show the ranges of each species for the eastern United States but not for the Dismal Swamp region specifically. The information is accurate and presented in a mostly non-technical style.

Wisconsin Herpetology: A Bibliographical Update with Taxonomic, Subject, and Geographic Indices, by Dreux J. Watermolen. 1992. Wisconsin Department of Natural Resources. Wisconsin Endangered Resources Report series installment number 87. (Available at no cost from Bureau of Endangered Resources, Wisconsin Department of Natural Resources, P.O. Box 7921, Madison, Wisconsin 53707, USA; telephone 608-266-7012).

This publication updates the 1987 *Wisconsin Endangered Resources Report No. 28*, and is intended to assist the research efforts of Wisconsin herpetologists and resource educators and to compliment the activities of the Wisconsin Herpetological Working Group. The bibliography includes 144 technical and popular references that deal with all aspects of Wisconsin's native amphibian and reptile species. Some items refer to physiological, taxonomic, or other studies in which Wisconsin specimens were used. The indices following the bibliography provide cross-reference by subject, taxonomic group (genus), and geographic locality (county), and direct the user to specific works by a numeric code.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). ***HR*** especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Life History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints.

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc., 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Life History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles, Techniques Articles, Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes, and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of three reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Life History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

Featuring . . . Reptilian Behavioral Ecology: A Symposium In Honor Of Charles C. Carpenter • Auction and Gourmet Beverage Tasting • Faculty: Free Raffle Tickets If You Bring Duplicate/Extra Offprints For Students (and save your office, too) • Students: The Great Reprint Scavenge • Field Trips: Thursday August 12th (including Herping with Joe Collins) • Tours of Indiana University's Axolotl Facility. *Additional details in March 1993 issue of HR.*

Instructions for Completing the Abstract Form

ABSTRACTS ARE NEEDED FOR EACH PAPER AND EACH POSTER. READ THESE INSTRUCTIONS BEFORE COMPLETING THE ABSTRACT FORM BELOW.

1. Compose abstract to fit inside rectangle below. Type a draft on a separate sheet of paper to be sure it will fit. Your abstract will be slightly reduced but otherwise appear exactly as you submit it. Leave 1/4" margins from the edges of the box. Do not exceed the space in the rectangle (or 200 words, whichever takes less space). Do not use fewer than 12 characters per inch.
2. Use the following format:
   First line—name(s) of author(s)
   Second line—address of author(s)
   Third line—title in all capital letters
   Fourth line—indent and begin text of abstract
3. Use the asterisk to denote the person who will make the presentation. Example:
   Frogs, I. C., and R. U. Curious*
   Herpetological College, Happy Valley, PA
   EFFECT OF ACID RAIN ON ANURAN DNA
   Frogs and tadpoles were collected from vernal ponds in Centre County. Acidity of pond water was measured by . . .
4. Use an electric typewriter or laser printer. Do not use a dot matrix printer.
5. Return your abstract form, unfolded, with one copy. Placing the abstract between piecies of cardboard will reduce the possibility of damage in the mail. If necessary, the abstract can be submitted on bond paper in rectangle of the same dimensions as the form provided.
6. Be sure that the abstract is informative: Consider inclusion of problem, methods (if pertinent), results, summary, and conclusions. Do not simply write, "Results are discussed."
7. Papers (except in symposia) are limited to 12 minutes for presentations and 3 minutes for discussion. Posters are not to exceed 4 feet x 4 feet.
8. THE DEADLINE FOR RECEIPT OF ABSTRACTS IS 15 MAY. (Honest)

( ) Paper ( ) Poster Special Audiovisual Needs _____

Are each of the authors students? _____

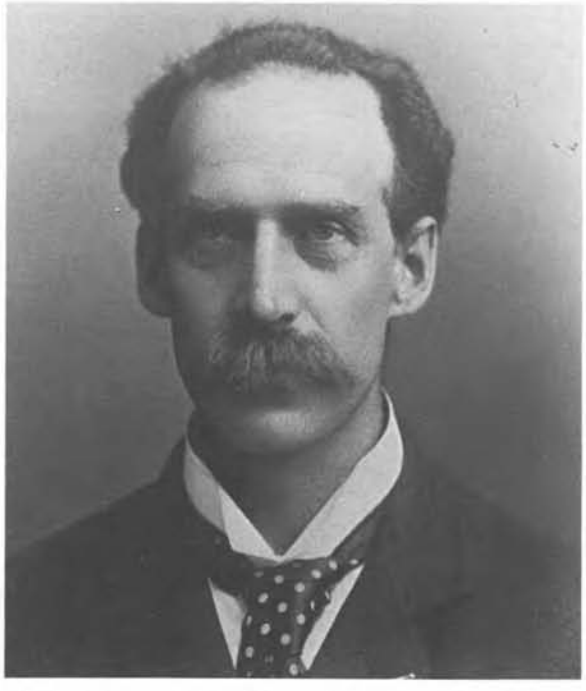
The Society for the Study of Amphibians and Reptiles Announces
A Facsimile Reprint to Commemorate the Second World Congress of Herpetology (Adelaide 1993)

THE REPTILES AND AMPHIBIANS OF SOUTH AUSTRALIA



by Edgar R. Waite

with a new introduction by Michael J. Tyler and Mark Hutchinson

WAITE'S WELL-KNOWN BOOK WAS THE FIRST AND IS still the only complete review of the herpetofauna of any Australian state. Published in 1929, it covers 112 species of reptiles and 12 species of amphibians, each described in detail, including size, distribution, and habits. There are 95 individual photographs, numerous line drawings showing diagnostic features, and keys to the genera and species.

Edgar Waite (1866–1928) was an English naturalist who emigrated to Australia in 1893 to join the staff of the Australian Museum in Sydney. He moved to New Zealand in 1906 as director of the Canterbury Museum and in 1914 became director of the South Australian Museum in Adelaide. Although primarily an ichthyologist, he also published numerous papers on herpetology. Waite's popular book on snakes, issued in 1898, was probably the first pocket-sized field guide published on reptiles. His *magnum opus* was his book, "Reptiles and Amphibians of South Australia," which although out-of-print for decades is still highly useful and sought after.

The reprint includes a new introduction by Michael J. Tyler (University of Adelaide) and Mark Hutchinson (South Australian Museum), who provide a biography of Waite that gives the historical context for the book. They also include an extensive annotated list of Waite's species names, showing the current taxonomy and correcting some errors in Waite's identifications. Waite was also an accomplished artist and included in this reprint is a watercolor of several frogs, reproduced in full color.

Specifications: 290 pages, 6 x 9 inches (15 x 23 cm), 95 photos, portrait of Waite, bound in library-grade cloth. To be published in April 1993.

PRICES AND ORDERING

- Pre-publication price (before 15 March 1993) to SSAR members ..... US$28
- Price to other persons and to institutions $35

Packing and shipping per volume: within the USA, add $2; to other countries, add $4.

Send orders to: Dr. Robert B. Aldridge, SSAR Publications Secretary, Department of Biology, St. Louis University, St. Louis, Missouri 63103, USA (*telephone* 314-658-3916; *fax* 314-658-3117). Overseas customers must pay in USA funds using a draft drawn on an American bank (include additional funds to cover bank conversion charges) or by International Money Order. MasterCard and VISA are acceptable (provide account number and expiration date); a 5.25% bank charge will be added to your account.

A complete list of SSAR publications ❑ and applications for Society membership ❑ are available from Dr. Aldridge by marking the boxes and returning this form to him at the above address.

SSAR BUSINESS

SSAR Annual Meeting: El Paso 1992

The University of Texas at El Paso played host to a hoard of over 400 herpetologists between 2 and 6 August 1992, as SSAR held its 35th annual meeting. The meeting was co-hosted by UTEP, El Paso Community College, and Sociedad Herpetología Mexicana, with Jerry Johnson (EPCC) and Carl Lieb (UTEP) co-chairs of the local committee.

The unofficial start of the meeting was the annual meeting of the SSAR Board of Directors, held on 2 August 1992, between 1000 and 1815 hours (MDT), in the conference room of the downtown Travelodge Hotel. Attendance at the meeting was larger than recent tradition would suggest: all twelve officers and Board members were there, as were at least one editor from each of the Society's publications, several coordinators, and chairs or representatives of virtually all committees; an additional 10-12 interested members rounded out the attendance. A summary of business conducted was later presented at the Business Meeting (see below).

Presentations

The official call to order came from local Co-chair Carl Lieb at 0915 hours on Monday, 3 August 1992, at which point we were welcomed to UTEP by the Associate Vice-President for Research and Graduate Studies, Julie Sanford. The welcoming was followed by a brief memorial to Ruth Zantzinger, who passed away last autumn; Ruth was a frequent volunteer when SSAR needed assistance (see Herpetol. Rev. 23:3-4, 1992). President Moll then introduced our Keynote Speaker, Linda Maxson, of Pennsylvania State University, who presented "A Random Walk Among the Anura." Following the keynote address and the requisite announcements, Mike Tyler made a brief presentation on the upcoming Second World Congress of Herpetology, to be held 29 December 1993 to 6 January 1994 at the University of Adelaide, South Australia, Australia.

Dr. Maxson's address began by noting that her first field study was to work out the genetics of color polymorphism in *Hyla/Pseudacris regilla*. In this system, the final morphology is the result of an unknown process or processes acting on the genotype. Concern about the unknown part of that equation led her to molecular techniques. The bulk of the address discussed examples of how the techniques of microcomplement fixation, by robustly estimating differences in amino acid sequences, allow the uncovering of heretofore hidden relationships among taxa, or, since amino acid substitution occurs at a reasonably steady rate, the timing of separation events. The practical biological significance of such studies is (for just a couple of examples) to recognize that there are many more species than we are aware of in the Amazon Basin, or to clarify biogeographic problems.

There were nearly 90 papers contributed by 145 authors in a dozen sessions between 1330 hours, 3 August 1992 and 1200 hours, 6 August 1992. In addition, nearly 80 authors presented 40 posters during three sessions. Three symposia (Chelonians, Conservation, and Subspecies), involving 65 authors and 44 papers, and a Regional Societies Conference rounded out the official scholarly presentations. There was also an informal, students-only poster session (no prepared materials allowed, on-the-spot graphics only) to encourage interaction among students.

Sociality

Hosts Johnson and Lieb were careful to plan for our less scholarly needs as well, a point to which the busy schedule of additional events attests. These efforts by the local committee were well appreciated. We were welcomed to the hospitality of El Paso by an evening social at the Centennial Museum, on 3 August. This was followed later in the evening by a new incarnation of an old SSAR tradition. The revived event, now christened "President's Herpetological Travelogue," was an only slightly more organized version of the sit-around-viewing-slides-of-exotic-herps evening entertainment of not so many years past. James Dixon entertained us with a view of the herps of Venezuela, Aurelio Ramirez-Bautista offered glimpses of the herps of Jalisco, México, and SSAR President Ed Moll treated us to the turtles of India. Those of us with the interest but no opportunity to visit such exotic shores were introduced to their herpetofauna vicariously—and thoroughly enjoyed it.

The next evening, Tuesday, presented a "Fajita Fiesta" on the patio of the UTEP Union, an event much appreciated by the pilgrims assembled in a region of the country where Mexican food is done right. This was followed by the annual SSAR Auction. Master auctioneer Joe Collins skillfully coaxed greenbacks from the wallets of attendees to help support various SSAR projects. He was ably assisted by the following individuals, whose efforts helped ensure another successful auction: Suzanne Collins, Jerry and Kathy Johnson, Doug Taylor, Gabriel Valles, Chrystal Mars, Steve Christman, Jeanne Young, Kelley Smith, Laurie Dohm, Ellin Beltz, and the Incomparable Laura. With all of the food, the liquid refreshments, and the wild bidding, to say we had an entertaining evening would be the epitome of understatement.

Another long-term SSAR tradition, the live exhibit of local amphibians and reptiles, included an exhibit of old meeting t-shirts. Held at the Centennial Museum, the live exhibit was co-sponsored by the Chihuahuan Desert and the El Paso Herpetological Societies, and offered dozens of local species to the photographers among us. Also available throughout the meeting, were a juried show of herpetological art at the Museum, and a number of commercial exhibits, offering such items as books, arts and crafts, and research and care equipment, in the Union.

The annual multimedia event rounded out the week's events on Thursday, 6 August. "Amphibians of the Appalachians" and "Herpetology of the American West" by David Dennis and Eric Juterbock, and "Herpetologists Past and Present" by Kraig Adler and Dave Dennis, played to a large and enthusiastic audience at the Union Theater.

Business Meeting

The Annual Business Meeting was called to order at 1700 hours, Wednesday, 5 August 1992, in the Union Theater at UTEP, by President Ed Moll. After welcoming everyone to the meeting, he gave a very brief summary of the inter-society liaison meeting held this June in Urbana, at which a 1994 meeting in Athens, Georgia was discussed. As a result of requests from the incumbents, committees have been formed to locate individuals to serve as Treasurer and Publications Secretary (both Board positions), and *Journal of Herpetology* Editor.

In order that the Chair of the Resolutions Committee could be certain to catch the bus to the Juarez Racetrack, the resolutions (see below) were then read before any other business was conducted. All resolutions were passed unanimously by the assembled members.

Secretary Juterbock presented a very brief summary of business conducted at the Board Meeting, since the significant items were reported elsewhere (see below). Treasurer Taylor announced that SSAR was in good financial shape, and that the budget was balanced without having to raise dues.

A brief summary of editorial and committee business was presented. *Journal of Herpetology* is on time and under budget; there is no lag time, the flip side of which is that there can be problems filling each issue if authors are slow with revisions; the number of submissions is increasing, especially from authors outside the U.S. (now approximately 50%). *Herpetological Review* introduced a new format this year, and a 20-year index is now available. The *Catalogue of American Amphibians and Reptiles* notes only a significant problem in soliciting accounts. *Facsimile Reprints in Herpetology* will issue Fauvel's "Alligators in China" (1879) in autumn 1992; *Contributions to Herpetology* issued Leviton et al.'s "Handbook to Middle East Amphibians and Reptiles" in March 1992 and will issue "Herpetology: Contemporary Research on Amphibians and Reptiles," the First World Congress plenary lectures, in December 1992. *Herpetological Circulars* issued Snider and Bowler's "Longevity of Reptiles and Amphibians in North American Collections" in June 1992. Committee work of note included the Grants-in-Herpetology Committee discussing a definition of "student" (i.e., "graduate student" would appear to exclude research by undergraduates); the Annual Meetings Committee is pursuing a meeting in 1995 in Lincoln, Nebraska.

Craig Nelson (1993 Local Committee Chair) reported on plans for the 7-12 August 1993 meeting in Bloomington, Indiana. Indiana University will host the meeting. Be sure to follow *Herpetological Review* for news of the plans and descriptions of the site.

Kraig Adler, reporting for the Nominating Committee, announced the candidates for terms of office beginning in 1993. President-elect: Lynne Houck and Rodolfo Ruibal; Secretary: J. Eric Juterbock; Treasurer: Douglas H. Taylor; Director: Gregory Pregill and Dianne B. Seale; Director (non-U.S.): David M. Green and Robert Johnson. With no nominations from the floor, Bob Hansen moved (Dale Belcher seconded) to close the nominations; the motion carried without dissent.

The only item of old business discussed was the revision of the SSAR Bylaws. The Board had previously approved amending the Bylaws to make them gender-neutral. Copies of the proposed changes were distributed to attendees, who also approved the changes. The proposed amendments will be voted on by the membership in the 1992 election. Finally, at about 1750 hours, President Moll presented the official SSAR Presidential Gavel to President-elect Fritts, who adjourned the meeting.

Resolutions

Societies Salute Mexican Government Progress On Sea Turtle Conservation (Joint)

WHEREAS the world's populations of sea turtles have seriously declined as a consequence of direct human take for food and curios and incidental mortality associated with other fisheries; and,

WHEREAS México has historically supported the highest species richness and abundance of sea turtles in the western hemisphere, with all but one of the worldwide species nesting on its shores; and,

WHEREAS the Government of México took action in 1990 to end all directed fisheries for sea turtles in México, and has taken action to end exportation of sea turtle products; and,

WHEREAS the Government of México has announced that beginning in September 1992 Mexican shrimp fishing fleets will be required to use turtle excluder devices (TEDs) to reduce the rate of incidental capture of sea turtles; and,

WHEREAS the Government of México has taken concerted and consistent action to protect nesting Kemp's Ridley turtles on the nesting beach at Rancho Nuevo; and,

WHEREAS the Government of México has taken other steps to encourage and support international efforts to conserve sea turtles;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles (SSAR) and the Sociedad Herpetología Mexicana, professional scientific societies devoted to the study of amphibians and reptiles, salute and applaud these conservation actions of the Government of México and President Salinas de Gortari; and, be it further

RESOLVED that these Societies encourage the Government of México to vigorously enforce these conservation-oriented regulations.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles and the Sociedad Herpetología Mexicana, 5 August 1992 at their joint Annual Meeting.

Honoring Outgoing SSAR Officers and Editors

WHEREAS the following individuals have given freely of their time, skills, insight, and knowledge to the Society for the Study of Amphibians and Reptiles in this past year, thereby advancing its goals and furthering its growth and development as an international society; and,

WHEREAS these persons have, in the finest tradition of the Society, passed on to their institutions as much of the associated costs of this service to SSAR as was possible (even in a stressful budget year!); and,

WHEREAS the Society hopes that by lauding them here it may encourage them to serve again at some future time; and,

WHEREAS said Society is greatly indebted to these persons for their continual efforts in its behalf; and,

WHEREAS the Society urges these persons not to ride off into the sunset, but rather to, with or without official titles, continue to be available as resources to help those who follow better guide SSAR;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles offers its most sincere thanks to the following persons who have served in these capacities:

A. DALE BELCHER— Director
WILLIAM S. BROWN— Immediate Past-President
JAMES L. CHRISTIANSEN— Director and Chair, Long-Range Planning Committee
JOSEPH T. COLLINS— Annual Meeting Sites Coordinator
CARL ERNST— CAAR Section Editor
F. WAYNE KING— CAAR Section Editor
LINDA R. MAXSON— President and Chair, 1991 Local Committee
MARGARET STEWART— Chair, Nominating Committee
JAIME VILLA— Journal of Herpetology Editorial Board

Adopted by the Society for the Study of Amphibians and Reptiles 5 August 1992 at its Annual Business Meeting.

Thanking The Local Committee (Joint)

WHEREAS hundreds of herpetologists from several countries have assembled in El Paso for this joint meeting of the Society for the Study of Amphibians and Reptiles and the Sociedad Herpetología Mexicana; and,

WHEREAS Local Committee Chairs Carl Lieb and Jerry Johnson, ably assisted by Joyce Lieb, Kathy Johnson, Bob Webb, Margaret Jackson, Travis LaDuc, members of the Chihuahuan Desert Herpetological Society and of the El Paso Herpetological Society, the El Paso Centennial Museum, and many others, performed a great service for the SSAR and the Sociedad Herpetología Mexicana by agreeing to undertake the arduous task of hosting this meeting; and,

WHEREAS the University of Texas, El Paso has provided a congenial setting for this meeting; and,

WHEREAS this meeting has provided the second major opportunity for these two societies to extensively mingle and for our members to learn from one another;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles and the Sociedad Herpetología Mexicana offer their most sincere thanks to these persons who worked so hard to make this meeting a success.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles and the Sociedad Herpetología Mexicana, 5 August 1992 at their joint Annual Meeting.

Kennedy Student Award

The 1992 Kennedy Student Award, for student-authored papers published in volume 25 of the *Journal of Herpetology* is "Growth rates and ages at maturity of sympatric scincid lizards (*Ctenotus*) in Central Australia" by Craig James. The paper is credited to the School of Biological Sciences, University of Sydney; Craig's major professor was Dr. Richard Shine; his present address is: CSIRO Division of Wildlife and Ecology, P.O. Box 84, Lyneham, A.C.T., 2602, Australia.

The Award Committee noted both the high quality and the exceptionally high number of papers submitted this year. SSAR congratulates Craig James for his fine paper.

Seibert Awards

The first annual Seibert Awards were presented at the 35th Annual Meeting of the SSAR in El Paso, 2-6 August 1992. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). The awards recognize outstanding student presentations at the annual meeting.

The winners: First Place—Bryan Windmiller (Tufts University), "Oriented dispersal in juvenile green frogs, *Rana clamitans*." Second Place—Mary Rybitski (Virginia Institute of Marine Science), "Organochlorines in Atlantic sea turtles." Honorable Mention—E. L. Blankenship (Auburn University), "Feeding trial of the smoky jungle frog larva (*Leptodactylus pentadactylus*)." SSAR congratulates these students for their fine presentations.

Announcement: ASIH, HL, And SSAR Position Statement On Environmental Problems

In late 1991 the National Research Council's Committee on Environmental Research asked numerous professional societies to comment on specific questions regarding environmental research and funding problems in the United States. Representatives of the three herpetological societies (ASIH, HL, SSAR) drafted a single position statement that was submitted to the NRC committee on 10 January 1992. This statement contains many of the comments provided in response to a Committee for the National Institutes for the Environment questionnaire that was mailed to all HL members (and therefore many ASIH and SSAR members) in September 1991. The position statement itself will be published in *Copeia* 1992(4).

New Life History Notes Section Editor

Randy Jennings has assumed the section editorship for Life History Notes effective 1 January 1993. He takes over for Steve Corn, who has accepted the position of Editor-in-Chief of *Northwestern Naturalist*. Steve's efforts on behalf of *HR* are sincerely appreciated. All Life History Note manuscripts should be sent to:

Randy D. Jennings
Section Editor, Life History Notes
Barrick Natural History Museum
University of Nevada, Las Vegas
4505 Maryland Parkway
Las Vegas, Nevada 89154-4012, USA.

IN MEMORIAM

Charles Mitchill Bogert
June 4, 1908 — April 10, 1992

Science lost a world-class herpetologist with the recent death of Charles "Chuck" Mitchill Bogert. Because a complete bibliography of his publications will be published in *Herpetologica*, and a review of his life and accomplishments will appear in other obituaries, I shall confine my remarks to a brief chronological sketch of his career, and then concentrate on Chuck Bogert as the man I knew and called a close friend for more than half a century.

Bogert was born at Mesa, Colorado, but his family later moved to Los Angeles, California, where he received much of his education, including his preparation for a degree of Bachelor of Arts from the University of California at Los Angeles in 1934 and a Master of Arts in 1936. Meanwhile he served as a teaching assistant and worked in national parks during summer recesses. His early mentors were Laurence M. Klauber and Raymond B. Cowles, the latter of whom became one of his life-long friends. From 1936 through 1940 he was Assistant Curator in the Department of Herpetology at the American Museum of Natural History. After the death of G. K. Noble late in 1940 he was in charge of the department, becoming Curator in 1943 and subsequently Chairman. He retired at the end of 1968, when he moved to Santa Fe, New Mexico. His thermal investigations on temperature requirements of reptiles and amphibians started in 1938, and his faunal work in México, which was to continue for decades, began in 1939 with the assistance of a Grant-in-Aid from the Carnegie Corporation. His first major paper, other than the published updating of his thesis on the snake genus *Salvadora*, appeared in 1940 (Results of the Vernay Angola Expedition . . . . Part I, Snakes). Bogert took an active part in the internal affairs of the American Museum, serving on committees and in a number of other positions. In 1955 he was awarded a Guggenheim Fellowship for the study of reptilian thermoregulation and amphibian vocalization. Because herpetology, as well as other disciplines, was dominated by systematics at the time, Bogert was pioneering with his behavioral studies.

He was the first President of the Herpetologists' League, but soon resigned when it became clear Major Chapman Grant considered that organization as his private domain. Bogert was elected to several offices in the American Society of Ichthyologists and Herpetologists, and was its President in 1952-1954. In 1966 he received an honorary LL.D. from his alma mater, UCLA. Bogert traveled and collected widely through North and Middle America, the Bahama Islands, and Ceylon. He married Martha Meredith Ruby, one of his former students, on February 19, 1937. Their two children were Dereth Margaret (deceased) and Patricia Heaton (Patricia B. Holbrook).

Charles M. Bogert was a prolific writer throughout his professional life, and he was adept at penning things for the layman as well as for his more erudite reading audiences. He produced a steady flow of publications based on his own research and fieldwork, his broad knowledge of herpetology and its literature, and his willingness to respond to the lay public. He answered many queries and comments that were addressed to Natural History Magazine, and which printed his replies. His former colleagues in the Department of Herpetology, Charles W. Myers and Richard G. Zweifel (*Herpetologica*, in press) list 65 scientific contributions, 151 titles under "Abstracts, Reviews, and Popular Publications," and four commercially available records, the sounds for which Bogert recorded in the field, often with the help of his wife.

FIG. 1. Portrait of Charles Mitchill Bogert during the 1950's. Courtesy of the American Museum of Natural History.

Although the list of Bogert's strictly scientific publications may seem surprisingly short, cognizance must be taken of the fact that

many of his contributions were exceptionally long and definitive works, several of them co-authored with others. They embraced a wide spectrum of subjects, such as African snakes, cobras especially, *Lanthanotus*, the Helodermatidae, the herpetofauna of Sonora, thermoregulation of reptiles, and the influence of sound on the behavior of amphibians and reptiles. His scientific output accounted for more than 1700 printed pages, an impressive total.

Bogert was meticulous. He strove for thoroughness and perfection. For example, he took the time and effort to seek out original references and was not content, as were some of his contemporaries, to copy from others who presumably had verified facts and dates, but who sometimes made mistakes. He put in long hours of overtime, often carrying a briefcase full of work to his home for added attention at night. He was critical of sloppy writers, and he did not hesitate to say so.

Just when I first met Chuck Bogert I have now forgotten. Possibly it was at a herpetological meeting, but more likely I paid him a visit at the American Museum. We both had arrived in the East in the mid-1930's. Our correspondence, which occupies more than six inches in my archival files, began in late 1937, but there is no mention of an earlier meeting.

My herpetological interest at the time, and for many years afterward, was largely with water snakes, then all placed in the genus *Natrix*. The rather extensive collection of those serpents at the Museum offered much material useful for my studies. One day when I was in New York, I was busily counting scales on specimens of the red-bellied water snake, which Chuck had helped me dig out of the stored collection. Some time later he arrived with another rather large snake with a reddish venter and remarked, "Here's one we missed." I took it from him, examined it briefly, and said, "That's no red-bellied water snake. It's not even a member of the genus *Natrix*." Chuck responded, in mocked surprise, "It isn't! What is it then?" I didn't know. The scoundrel had hunted through the collection for a snake from some distant part of the world that superficially resembled the ones I was studying. He was testing me out. I didn't mind, and I had a good private laugh about it later. But when he tried the same thing on certain other persons, they resented it and were quite annoyed. Evidently I passed the test because a short time later I was notified I had been made a Research Associate of the Department of Herpetology, a privilege that I still enjoy.

It early became apparent that Chuck, at times, could be rude, even abusive, toward others. That surprised me at first, and I thought perhaps something had gone wrong to disturb his equanimity, or even that he had not slept well the previous night. Unhappily, it was chronic with Chuck, in that similar behavior cropped up now and then. The thought crossed my mind that perhaps there had been some happenstance in his life that made him feel the need to be irritable at times. To defend himself? Perhaps subconsciously? I learned recently that members of his family believe that such an unfortunate complex may have originated in his early youth. He became abrasive with me one day early in our association, and I responded in kind. He respected me for it and, although there were occasional later outbursts, we got along well thereafter. Regrettably, when others were subjected to similar treatment they did not always forgive him, and he made a number of enemies as a result.

I have heard so many conflicting stories about Bogert over the years that one might think he was a latter-day Dr. Jekyll and Mr. Hyde. On the negative side some people depicted him as a stern, forbidding ogre who lorded it over his subordinates. He could be scathingly critical. He seemed reluctant to compliment anyone on a good piece of work. He was quick to anger and slow to forgive.

On the other hand he was polite and helpful to visitors. He insisted on keeping up the Departmental bibliography of herpetology, and he supervised the maintenance of a well-curated preserved collection when both funds and staff were low. He was a good correspondent with many people, and he received honors from a number of prestigious organizations. He worked hard for long hours. He could be very kind and thoughtful at times. Ellin Beltz, columnist for the *Bulletin* of the Chicago Herpetological Society, vividly recalls her first encounter with him when she was very young. She and a bosom friend were both too small to see into the Museum exhibits. They remedied that difficulty by holding each other up briefly to have a look. They could not read the labels without jumping up and down, as she put it, like Mexican jumping beans. They were so noisy that Chuck left his office to investigate. He sized up the situation at once, procured a wooden box for them to stand on and then told them, whenever they were at the Museum, to knock on the door and ask for it. Bogert, who was always a tall, handsome, and imposing figure, later took the two little girls, who were especially fond of reptiles, for a behind-the-scenes-tour of his Department.

Chuck normally did everything in his power to help me. He looked up references for me among the huge literary resources of the Museum, he critically reviewed some of my manuscripts, and when I visited the Museum he made sure that I had access to everything I needed. We were prompt correspondents with each other and, when he received an inquiry from me, I was almost invariably assured of a card or letter in reply that he would mail the same day. When I asked to borrow specimens, they were packed and shipped almost as quickly. I owe much to Chuck who befriended me, guided me, and helped me to avoid mistakes in the days when I was trying to make a serious herpetologist of myself. In a sense he became *my* mentor.

It was Chuck Bogert who helped focus my attention on Mexican reptiles and amphibians. On August 26, 1946, he was in the field, with two companions, along the Río Nazas in Durango, when they collected a rather large water snake by shooting it. By camp light, that very same night, he composed a hand-written letter telling me about it that he mailed from Torreón the next day. I deeply appreciated his thoughtfulness which, although I didn't know it at the time, was to open a whole new vista for me. The Río Nazas is an isolated river that rises in the highlands of western Durango, flows chiefly eastward, and once emptied into the desert in western Coahuila. (The water is now almost entirely devoted to human use, chiefly in the Laguna District centering around Torreón, Gómez Palacio, and Ciudad Lerdo.) How did a water snake get into such a stream, one that went nowhere, so to speak? That question was to intrigue me for years. Chuck sent me the specimen as soon as he arrived home from México, and I managed a few years later to collect more of the same kind. In 1953, after a careful study of all pertinent material, I described *Natrix erythrogaster bogerti*, which is endemic to that single river system. My trip to the region and other parts of México in 1949 was stimulated by Bogert, and he later encouraged me to apply for financial support from the National Science Foundation. I was able to qualify for three consecutive grants.

On the subject of new taxa, Chuck named 27 during his long professional career, two of them new genera. Some 20 taxa were named for him, including my water snake and two new genera, *Bogertia* and *Bogertophis*. The first had an interesting origin. Bertha Lutz, an authority on Brazilian frogs, apparently sent a pair of geckos, which she had found near the Atlantic Coast, to Bogert for identification. He, in turn, sought help from Arthur Loveridge at the Museum of Comparative Zoology, who described them in

1941 as a new species and created the combination *Bogertia lutzae*, thus honoring two persons. Doubtless Loveridge was reciprocating inasmuch as Bogert had named a new African snake, *Meizodon loveridgei*, for him the previous year. Bogert, based on our friendship and also doubtless because I called the new water snake *bogerti*, named a salamander, *Pseudoeurycea conanti*, for me.

The other new genus dedicated to Chuck was *Bogertophis*, which was erected by Dowling and Price to accommodate the species of snakes, *rosaliae* and *subocularis*, which had long been assigned to the genus *Elaphe*.

Chuck always had a subtle sense of humor. The last taxon named for him was *Heloderma horridum charlesbogerti* Campbell and Vannini, for a new subspecies of that venomous lizard from a xeric area in eastern Guatemala. He thought it was a great joke—"the horrible Charles Bogert."

Based on his broad experience south of the border, Chuck taught me many things about México. Although I had visited the American Southwest a few times, I knew little about arid country and its plant and animal life. I suspected that the best time to be in the field was during the onset of the summer rains when "critters" of various kinds would emerge from estivation following the long dry season. He vigorously confirmed that supposition. By relating many of his experiences he gave me an insight on how to treat the *peones* in rural México, how to avoid being cheated in the markets, and how to bargain when necessary. My limited Spanish, which improved greatly when I had to use it for several summers in succession, was ample to cope with most problems. In short, Bogert was more than willing to share his information with me.

Inasmuch as Chuck continued to visit México regularly, it was inevitable that we should plan to meet and be in the field together. Our first such encounter was at Chapala, Jalisco, where my late wife, Isabelle, and I met Bogert and three students. We did some collecting, and Chuck introduced me to the large garter snake, *Thamnophis eques*, which occupies one of the water snake niches on the Mexican plateau and trans-volcanic belt. It was abundant but difficult to catch. Chuck also took us on shopping tours of Guadalajara and nearby Tlaquepaque, scarcely field work but interesting and useful nonetheless.

It was from Oaxaca de Juárez as a base that we spent more time with him and his wife, Martha, or "Mickey," as she is universally known to her friends. Chuck and John A. Moore had visited the area during the previous year, but in 1961 and for a full decade afterward, the Bogerts spent their summers in Oaxaca, meantime developing a close rapport with Roy H. and Anita Jones, who operated the Oaxaca Courts, a first-class place for tourists to stay. It was much better than the average motel. Anita was an excellent manager, and she kept such a tight rein on her employees that their dining room was one of the few places in México where it was safe to eat and drink anything placed on the tables. From Oaxaca the Bogerts ranged out in all directions. He found a number of new species which he described, including a new genus of dwarf boa. They made sure that we saw the ancient ruins at Mitla and Monte Alban, but our most momentous excursion was an abortive attempt to find a freshwater lake along the Pacific coast near Puerto Angel. Did the west coast water snake, which was abundant in a lagoon near Acapulco, range that far southward and eastward? I wanted to know if possible.

Mickey elected to remain in Oaxaca, but Isabelle and I drove our Volkswagen Kamper and Chuck was accompanied in his field vehicle by two visitors, a Mr. and Mrs. Potter. The paved road terminated at Miahuatlán, and then we had a hundred miles of rough going to negotiate, over many knife-like ridges and down the steep, sinuous road of the escarpment. In some places, during afternoon thundershowers, we could see the dirt road washing away on its downward side, and we wondered if there would be enough room left for us to get through on our return trip.

We never found our objective, but we collected wherever and whenever we could. Chuck, who enjoyed social contacts and who also was a good raconteur and so well-informed about so many aspects of México, spent a large part of his time talking with the Potters. Both he and I collected frogs, but I caught the only snake, the only turtle, and the only two salamanders of the trip. When I twitted him about it, he accepted it good-naturedly, and there was no vituperative outburst as I had heard him direct at others who had managed to beat him in the field. Our Kamper, which was well stocked with food, became the "chuck wagon," and Isabelle found herself catering for five instead of two.

On our return trip Chuck demonstrated an aspect of his personality that was pixie-like, to say the least. Wild calla lilies were in bloom here and there at places where we stopped to rest and to try to find something to collect. Where a primitive lane met the almost equally primitive road along which we traveled, a young girl, perhaps seven or eight years of age, held a bouquet of lilies that she obviously hoped we would buy. Bogert stepped from his vehicle and told her in Spanish that he would take them if she would give him a kiss. She was shy, and an amusing tableau developed that lasted for several minutes and only terminated when she gave him a peck on the cheek as he leaned over. She grabbed the few pesos from his hand and ran as fast as she could to the safety of her nearby humble home, from which her mother had watched us. When we arrived back at the Oaxaca Courts with the lilies, Roy Jones blurted out, "Who's dead?"

The Bogerts loved Oaxaca so much that they hoped to retire there. They even bought some land, or thought they had, on which they planned to build a house, but Mexican law, plus a heavy dash of chicanery, thwarted them. Anita Jones had been born in México, of Dutch parents, and she was thus a Mexican citizen, and she could own property. The Bogerts, as gringos, had no such privileges. At almost the last minute their daughter, Patricia, found a nice house near her own in Santa Fe, New Mexico, which they bought sight unseen. They moved into it during 1968. Traces of Oaxaca quickly appeared in the form of *tapetes* and other objects skillfully prepared by a clever and intelligent weaver, Isaac Vásquez, of Teotitlán, a small village about midway between the city of Oaxaca and Mitla. Some of Isaac's creations still adorn my own home in Albuquerque.

The Bogerts settled in, and Chuck assembled his woodworking shop in one of the bedrooms. He was a skilled craftsman with his hobby of making boxes of inlaid wood of various kinds and colors. He also continued his interest in herpetology. He caught and marked many short-horned lizards, *Phrynosoma douglassii*, in the open land around their house. He contracted to prepare a report on the herpetofauna of the Los Alamos Natural Environmental Research Park, and he wrote an exhaustive manuscript on the subject which, probably because of its great length, was never published. Meantime, dissatisfied with the conclusions reached in his Master's thesis on *Salvadora*, especially in view of the accumulation of new material from critical localities, he hoped to produce a monographic study on the genus. He even patched up his misunderstanding with Charles H. Lowe, of the University of Arizona, and was able to examine the pertinent specimens at that institution. Also, when the Society for the Study of Amphibians and Reptiles expressed a desire to reprint the Bogert and Martín del Campo opus on the Helodermatidae, he agreed to prepare an introduction updating that major contribution to herpetology. Alas, neither was ever finished.

Once he was away from the stimulation of his colleagues at the American Museum, Chuck turned more and more to other things, notably traveling and spending much time conversing with local friends, as well as many others who visited Santa Fe and were guests in their home. With Mickey he made several trips to Africa, as well as one to New Guinea and Australia, not to pursue research, but to see and enjoy distant parts of the world. It was interesting to note the change in decor at their home. For the first many years of retirement, Isaac's weavings and Mexican arts and crafts and utensils were very much in evidence. Once the Bogerts began traveling extensively, African artifacts gradually replaced their memories of México.

Chuck produced a few short papers during his retirement, but the old drive and productivity were gone. He continued to correspond with friends and colleagues, we visited back and forth occasionally, but we had to use the telephone for communication after I began spending large blocks of time in Tucson, Arizona, as I pressed forward with the Howard K. Gloyd and Conant tome that was eventually published as "Snakes of the *Agkistrodon* Complex, a Monographic Review."

Disaster overtook Chuck on April 17, 1988, when he suffered a stroke that greatly impaired one of his legs. He was sent to Albuquerque for therapy, where Kathryn Gloyd and I visited him, and later in Santa Fe when he was getting around on a walker. It was all downhill from the day of his stroke. Others followed at intervals. His fingers became so numb that he could use the typewriter only in the afternoon after they had limbered up, and then only with liberal applications of liquid paper to white out his mistakes. How extremely frustrated he must have been after such a long and distinguished career. Finally, on April 10, 1992, he had the courage to end it all and to eliminate the exhausting, almost 24-hour duty to which his faithful and beloved wife had been subjected for almost four years. He was thoughtful to the end and delivered the fatal bullet into himself in such a way as to cause no bloodshed.

Mickey Bogert recently scattered half his ashes on a hillside overlooking Oaxaca. The other half was committed to the soil of the Chiricahua Mountains of Arizona, one of his favorite places in the entire Southwest.

FIG. 2. C. M. Bogert recording at Schaeffer's Pond on the Palisades above Tenafly, New Jersey, ca. 1961. Photograph by Richard G. Zweifel.

Charles M. Bogert made an outstanding name for himself, and his many important scientific contributions are an enduring memorial to him as a dedicated herpetologist. Like so many of his other friends and admirers, I deeply mourn his passing. His career and accomplishments were unique in many ways.

Acknowledgments.—I am deeply grateful to Martha R. Bogert for her help in preparing these recollections of Chuck. Others who assisted in various ways are: Kraig Adler, Ellin Beltz, Charles W. Myers, Manny Rubio, Norman J. Scott, Jr., and Richard G. Zweifel.

NEWSNOTES

1993 CHS Herpetological Grants Program

The Chicago Herpetological Society announces the CHS Herpetological Grants program to award financial support for herpetological research, education, and conservation. Eight awards of up to $500 each will be available. Interested parties may apply for a grant in any one of the following categories:

1) Illinois Herpetology
2) Graduate Student Research in Herpetology
3) Undergraduate Research in Herpetology
4) Field Studies in Herpetology
5) Conservation
6) Captive Management, Husbandry, and Propagation

An attempt will be made to award grants in each category, but depending on the applications received, not all categories may receive awards. Some categories may receive more than one award. The Grants Committee reserves the right to reassign the category under which a given proposal is submitted. If applications are lacking, fewer than eight awards may be distributed.

Applicants must be CHS members. In accepting a grant, the recipient agrees to abide by all state and federal laws, to submit a written summary at the end of their work for publication in the CHS *Bulletin*, and to acknowledge the CHS in any publications that result from their subsidized research. Recipients are encouraged to submit their work in article form or as a CHS monthly meeting program.

Applications should include the following:

1) Statement of proposal objectives.
2) Description of materials and methods.
3) Complete budget, not to exceed $500.
4) Brief resumé of the applicant, if an individual. If the applicant is an organization, background information on the organization should be included.
5) A completion date for the project.

Applications must be typed, double spaced, and submitted in duplicate. Applications should be kept brief; proposals longer than four (4) pages are discouraged. All applications must be received by 1 March 1993, and awards will be announced by 1 May 1993.

It is the goal of the Grants Committee to award grants to a

variety of applicants; enthusiastic amateurs will receive equal consideration with professional herpetologists and graduate students. Topics including Illinois herpetology, captive husbandry and propagation, and those which may translate into quality CHS *Bulletin* articles or monthly meeting programs are favored, though not requisite.

Submit applications to:

CHS Herpetological Grants
Chicago Herpetological Society
Field Museum of Natural History
Division of Amphibians and Reptiles
Roosevelt Road at Lakeshore Drive
Chicago, Illinois 60605, USA.

Or contact Thomas G. Anton, 1993 Grants Committee Chair, at (708) 869-8219, or (312) 922-9410 ext. 271.

Summer Course In Amphibian Cytogenetics At Highlands Biological Station

The Highlands Biological Station, located in the Blue Ridge Mountains of southwestern North Carolina, is offering a course in Amphibian Cytogenetics, to be taught by Stanley K. Sessions of Hartwick College, during the period 7-18 June 1993.

Topics to be covered include chromosome banding, preparation of karyotypes and idiograms, analysis of meiosis, microspectrophotometry, genome size, and lampbrush chromosome preparation.

The course is designed for advanced undergraduates, graduate students, and professionals. Three semester hours credit is available through either Western Carolina University or the University of North Carolina at Chapel Hill. The course may also be taken on a non-credit basis. For further information and application forms contact:

Highlands Biological Station
P.O. Box 580
Highlands, North Carolina 28741, USA
Tel. (704) 526-2602.

SWRS Volunteer Opportunities

Approximately 20 volunteer positions are open in 1993 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between 15 March and 1 November 1993. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by 15 February 1993, summer volunteers (June–August) by 1 April 1993, and fall volunteers (September–November) may apply any time.

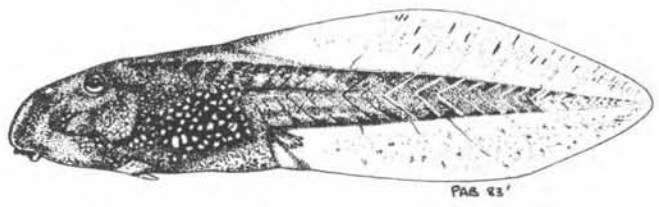
For applications, write to:

Dr. Wade C. Sherbrooke, Director
Southwestern Research Station
American Museum of Natural History
Portal, Arizona 85632, USA
Tel. (602) 558-2396.

AAZK Grants Available

The American Association of Zoo Keepers announces the availability of two $750 research grants in the field of zoo biology. The deadline for submissions is 1 March 1993. Interested applicants should direct their inquiries to:

Sue Barnard
AAZK Research/Grants Committee
Zoo Atlanta
Department of Herpetology
800 Cherokee Avenue, SE
Atlanta, Georgia 30315, USA.



Smithsonian Research Fellowships

The Smithsonian Institution announces its research fellowships for 1993-94 in the Biological Sciences. Smithsonian Fellowships are awarded to support independent research in residence at the Smithsonian in association with the research staff and using the Institution's resources. Under this program, senior postdoctoral fellowships of three to twelve months, pre- and postdoctoral fellowships of six to twelve months, and graduate student fellowships of ten weeks are awarded. Proposals for research in the following areas may be made: animal behavior and pathology; ecology; environmental studies; evolutionary biology; marine biology; natural history; paleobiology; systematics; and tropical biology.

Applications are due 15 January 1993. Stipends supporting these awards are $26,000 per year plus allowances for senior postdoctoral fellows (individuals who have the Ph.D. for more than seven years); $21,000 per year plus allowances for postdoctoral fellows; $13,000 per year plus allowances for predoctoral fellows; and $3,000 for graduate students for the ten-week tenure period. Pre-, post-, and senior postdoctoral stipends are prorated on a monthly basis for periods less than twelve months.

Awards are based on merit. Smithsonian fellowships are open to all qualified individuals without reference to race, color, religion, sex, national origin, age, or condition of handicap of any applicant. For more information and application forms, please write to (indicating area of proposed research and dates of degrees received or expected):

Smithsonian Institution
Office of Fellowships and Grants
955 L'Enfant Plaza, Suite 7000
Washington, D.C. 20560, USA.

MEETINGS

ASIH/HL/AES/ALFC 1993 Annual Meeting

The annual meetings of the American Society of Ichthyologists and Herpetologists (ASIH), Herpetologists' League (HL), American Elasmobranch Society (AES), and the Annual Larval Fish Conference (ALFC) will be held jointly on the campus of The University of Texas at Austin 27 May – 2 June 1993. The meetings are co-sponsored by The University of Texas at Austin and Texas A & M University. Scientific sessions will be held in Welch Hall and housing will be available in nearby Jester Center on the UT campus and at nearby hotels.

The meetings will include contributed papers and posters, exhibits, social activities, business meetings, and field trips. A special student paper symposium will be jointly sponsored by all participating societies. In addition, the following symposia are scheduled (organizers and sponsoring societies in parentheses): Biology of Feeding in Fishes, Amphibians, and Reptiles (Kiisa Nishikawa - HL/ASIH); Lizard Ecology: The Third Generation (Laurie Vitt and Eric Pianka - ASIH); *Sceloporus*: A Model System (George Middendorf - HL); Sexual Selection: What Has Been Learned From Ectotherms (Mike Ryan - ASIH/HL).

A meeting announcement will be mailed in December to members of the ASIH, HL, AES, and Early Life History Section of AFS. Others may request an announcement by contacting:

Diana Dobson
Thompson Conference Center
P.O. Box 7879
University of Texas
Austin, Texas 78713-7879
Tel. (512) 471-3123
FAX (512) 471-0647.

Sceloporus Symposium: Announcement And Call For Participation

As part of the ASIH/HL Meetings to be held 27 May – 2 June 1993 at the University of Texas at Austin, a symposium will be organized to address the following topics as they relate to the biology of *Sceloporus*: Systematics and Biogeography; Ecology and Demography; Reproduction and Physiology; and Behavioral Interactions.

Presentations are invited from all herpetologists studying *Sceloporus*. Interested persons should submit a tentative title and indicate a session affiliation. For additional information or to submit a title, please contact:

George Middendorf
Department of Zoology
Howard University
Box 887 Administration Building
Washington, D.C. 20059, USA
Tel. (202) 806-6933
FAX (202) 806-4564.

Symposium On The History Of Herpetology: Call For Papers

A symposium on the history of herpetology will be part of the Second World Congress of Herpetology at the University of Adelaide, South Australia from 29 December 1993 to 6 January 1994. The program is planned to include ten 15-minute talks contributing to the history of herpetology in the broadest sense. Contributors are welcome to submit papers dealing with the following topics:

— the development of herpetology as a recognized scientific field according to the modern standards (biographies of major herpetologists; major explorations and discoveries related to amphibians and reptiles over the world; foundations of major collections, departments, and laboratories devoted to herpetology; methods and techniques, etc.). Papers related to major themes (1. Evolution and Genetics; 2. Systematics and Distribution; 3. Physiology; 4. Ecology; 5. Ethology; 6. Conservation and Captive Care) are especially recommended;

— the origin, methods, aims, and results of what was once considered as herpetology in other periods of time and civilizations or cultures all over the world;

— data expressing knowledge and ideas about reptiles and amphibians at a common or traditional (pre-scientific) level (including positive and negative prejudices and their effects on the status of creeping creatures, on the development of their scientific study, on the relationship between humans and amphibians and reptiles). Such papers will emphasize anthropozoological analysis along with historical criticism.

Deadline: potential speakers should send complete details (title and summary of papers; affiliation and full address) as soon as possible.

Publication: papers (up to 10,000 words in length) recommended for publication by the committee of referees will be published in the collection of *Colloques d'histoire des connaissances zoologiques*.

For futher information or to submit papers, please contact:

Prof. Lilliane Bodson
rue Bois-l'Evêque 33
B-4000 Liège 1, Belgium

International Conference On Tortoise And Turtle Conservation

The American Museum of Natural History's Turtle Recovery Program and the New York Turtle & Tortoise Society will cosponsor Conservation, Restoration, and Management of Tortoises and Turtles—an International Conference. The conference will be hosted by the State University of New York, SUNY Purchase and held 11-17 July 1993.

The conference will provide a forum for a wide array of people concerned with conservation to critically assess current efforts and develop strategies for the future. Using turtles as a model, the conference will develop techniques that can be applied to the conservation of a wide array of flora and fauna. Conference participants will include representatives from the academic, business, government, and private sectors.

The Turtle Recovery Program is a joint initiative of the American Museum of Natural History and the IUCN-World Conservation Union Species Survival Commission. The program designs and implements turtle conservation programs around the world. The New York Turtle & Tortoise Society, one of the world's largest turtle groups, is dedicated to the conservation and preservation of turtles and tortoises and their habitats. The society is also committed to the promotion of the proper husbandry and captive propagation of turtles and tortoises.

For further information on the conference contact:

Craig Vitamenti
c/o The New York Turtle & Tortoise Society
163 Amsterdam Avenue, Suite 365
New York, New York 10023, USA
Tel. (212) 459-4803.

IHS 17th Annual Symposium: Announcement And Call For Papers

The International Herpetological Symposium, Inc. will hold the 17th Annual Symposium in Miami Beach, Florida, 17-20 June 1993. The IHS presents papers on herpetoculture, natural history, veterinary medicine, and other topics related to herpetology. Individuals interested in presenting a paper at this meeting should write to:

Richard Ross, MD
Institute for Herpetological Research
P.O. Box 2227
Stanford, California 94309, USA.

Tiger Salamander Symposium

The second symposium on the eastern tiger salamander (*Ambystoma t. tigrinum*) will be held on Friday, March 5, 1993 in East Hampton, Long Island, New York. The focus of the symposium will be conservation and management of the eastern tiger salamander. Featured events will include field trips on the evenings of March 4-5. If you are interested in participating or would like more information, please contact:

Andy Sabin
South Fork Natural History Society
P.O. Box NATURE
Amagansett, New York 11930, USA
Tel. (516) 267-7944.

Symposium On The Status And Conservation Of Turtles Of The Northeast

The Massachusetts Audubon Society will host a symposium on the status and conservation of the turtles of the northeast on Saturday and Sunday, 20-21 March 1993 at Worcester State College in Worcester, Massachusetts. Reports and papers will include state status reports, management projects, and biology of all northeastern species. For complete information, send a self-addressed, stamped envelope to: Massachusetts Audubon Society, South Great Road, Lincoln, Massachusetts 01773 attn: Turtle Symposium.

REGIONAL SOCIETIES

Czechoslovak Herpetological Society

The Czechoslovak Herpetological Society was founded in 1992. Czechoslovak herpetologists have been until now organized only in the Herpetological Section of the Czechoslovak Zoological Society. The main purposes for the foundation of the independent Society are as follows:

1) There are no professional herpetological institutions in Czechoslovakia. Hence, the Czechoslovak Herpetological Society (CSHS) is intended to be a platform for promotion and coordination of herpetological research (including preservation of herpetofauna) in Czechoslovakia.

2) The Czechoslovak Herpetological Society will support abovementioned herpetological research both scientifically and financially. It will enable contacts among its members (for instance, by means of informational pamphlets, scientific publications, organization of annual conferences), and it will take part in education of undergraduate students interested in herpetology. The Society will encourage its members to join the international herpetological community.

3) Membership is open both to natural persons and corporate bodies, from Czechoslovakia and from abroad, under the condition that they are interested in herpetology and follow the Statutes of the Society.

Further information may be obtained from:

Dr. Jirí Moravec
Department of Zoology
Národní muzeum
Václavské nám. 68
115 79 Praha 1
Czechoslovakia.

Finnish Herpetological Society

The keeping and breeding of reptiles and amphibians for study or hobby is a relatively recent development in Finland. The establishment of the Finnish Herpetological Society is the first official attempt to bring together the people involved in these activities in Finland.

Currently, FHS members are primarily interested in the following: 1) developing contacts both within Finland and abroad in order to expand their herpetological knowledge; 2) increasing the very limited number of species available to hobbyists in Finland; 3) ensuring appropriate treatment and welfare of captive animals; and 4) encouraging accurate and carefully planned attempts to breed captive herps.

FHS members would very much like to hear from similar organizations and their members around the world. All correspondence and assistance is welcomed. Correspondence should be directed to:

Mr. Mika Jansson
Ansaritie 2 A 9
SF-00300 Helsinki
Finland.

POINT OF VIEW

The Family Iguanidae: Disagreement With Frost And Etheridge (1989)

Frost and Etheridge (1989) presented "A phylogenetic analysis and taxonomy of iguanian lizards" resulting in recognition of nine families. Conant and Collins (1991) embraced this arrangement. However, I have studied iguanians for over three decades, in the field around the world, and at many museums, especially the Museum of Comparative Zoology (MCZ), and I cannot accept it.

The first issue for me confronting a drastic taxonomic fragmentation of this sort is "why"—in the sense of "what good does it do?" The taxa in higher categories (hereafter called simply higher taxa) such as families are words, not organisms. They are arbitrarily delimited by humans and serve only two purposes: facilitation of communication and facilitation of identification. To these ends higher taxa need to be unequivocally defined (as words) and readily recognizable wherever possible. The signal restraint is that a higher taxon must also be monophyletic as opposed to polyphyletic.

The evolutionary or synthetic systematist is willing to accept difficulties in correct recognition and identification if, by so doing, polyphyletic grouping is avoided. In the case of iguanian lizards, no issue of polyphyly arises. No one doubts that the Iguania is a monophyletic assemblage.

The cladistic notion of "paraphyly" is not a replacement for, or contradiction of, monophyly for the evolutionary or synthetic systematist. I fully accept that most any monophyletic higher taxon is or potentially can become paraphyletic (and remain monophyletic, of course). This occurs when some member lineage, a species, evolves beyond the defined limits of its ancestral higher taxon. For me, that is simply and obviously the way novel higher taxa originate (Simpson 1961:140-146). I do not believe cladistic and synthetic taxonomies can be reconciled in many cases, and reams have been printed on this subject (e.g., Mayr and Ashlock 1991; Wiley 1981). A succinct overview with which I can agree is provided by Nelson (1984).

In any case, while Frost and Etheridge provide equivocal evidence for paraphyly in the previous arrangement of three iguanian families, they present no compelling proof. Indeed, they present no new factual evidence at all and provide no definitive phylogeny.

Frost and Etheridge do place under one cover many of the scattered facts about iguanians many of us have known and considered for decades. These facts led us to adopt informal names for the groups Frost and Etheridge have elevated to formal families. I could not accept these groups even as valid subfamilies (e.g., Lazell 1989). No evidence has been presented to make me reconsider: I knew all that before and thought little of it then. The characters used by Frost and Etheridge are only a subset of those available and many, as shown in Table 1, do not bear up well under close scrutiny (see below).

Frost and Etheridge explicitly eschew "overall similarity," which is general resemblance or gestalt. I value gestalt highly and regard it, in the absence of evidence for polyphyletic convergence, as excellent evidence of relationship. Gestalt similarity results from the correspondence of myriad mensurable or meristic characters. Any of these can be quantified, evaluated as ancestral or derived, and used just exactly as Frost and Etheridge use qualitative characters such as gular fold complete or incomplete.

A generation ago a group of systematists built a briefly popular fad of classification around the codification and computation of gestalt. The notion was to count or measure literally everything possible about organisms and have a computer sort the organisms out. This group was called pheneticists or numerical taxonomists. Fundamental to their view was rejection of all subjective character weighting. The length of a lizard's tail was credited with exactly the same value as its number of limbs. This approach garnered many enthusiastic and vocal supporters, including many highly placed academicians generally judged to be quite intelligent (but see Orr 1992). Many of us were amazed that anyone would believe giving two characters equal weight was any less subjective than claiming one to be a dozen, or a million, times more valuable than the other. Frost and Etheridge also shun character weighting, thus subjectively rendering all characters equal.

Enlarged middorsal scales are certainly not the equal of zygodactyl foot. A classification which rejects gestalt as evidence for relationship within a monophyletic assemblage is unappealing to me. For example, chameleons are so bizarrely different in gestalt from all other iguanians and—indeed—all other earthly life forms that I would grant them a family of their own without hesitation. Fortunately, major qualitative characters back this up and I find no need to codify gestalt into specific characters in this case.

Conversely, tropidurines (or "Tropiduridae") and crotaphytines (or "Crotaphytidae") share many aspects of gestalt: they are rather similar looking lizards. Frost and Etheridge separate them as distinct families on the basis of three characters: femoral pores, gular fold, and S-condition of the nasal chamber in crotaphytines. The presence or absence of femoral pores varies within species of iguanians (e.g., *Polychrus marmoratus*); I cannot accept it as a family level character. Tropidurines lack a complete gular fold and have a primitive nasal chamber (see Table 1). I weight characters differentially and judge the differences between tropidurines and crotaphytines to be trivial in light of their overall gestalt resemblance and numerous other uniting features shown in Table 1.

The distinction of tropidurines from equally similar looking sceloporines (or "Phrynosomatidae") is even weaker, relying solely on the "sink trap" versus primitive nasal chamber. For me, that is simply not good enough for even subfamilial separation.

Frost and Etheridge settled on 30 characters for defining their proposed families. I regard some of their characters as utterly trivial. For example, hemipenes (present only in males, of course, and therefore of little use for identification) separate out no taxon. Similarly sternal rib attachments and sternal fontanelles are useless. Caudal vertebral features are not definitive for any group. Rugosity of skull roof signifies nothing more than a separation of oplurines from sceloporines and tropidurines (see Table 1).

All this contrasts dramatically to characters of gross morphology and histology of the tongue (Schwenk 1988), for example, which contradict the Frost and Etheridge scheme.

I reject the partition of continua in definition of higher taxa. That is, I insist on a gap in quantitative characters. For example, within the Iguania, colic folds or septa vary from zero to more than a dozen. The Iguanidae *sensu stricto* of Frost and Etheridge (iguanines previously) are separated from most other groups solely because they have from one to over a dozen folds or septa. Much of this distinction is in the phraseology. When one writes the character as present or absent it is specious. It sounds major and important. When one considers the actual structures in a spectrum of species (Iverson 1980) it becomes the artificial division of a continuum.

Most iguanians lack colic folds or septa. Iverson (1980) deter-

TABLE 1. The thirty characters used by Frost and Etheridge (1989) to define families of iguanian lizards. Abbreviated character names are given along the left. Fuller descriptions are supplied by Frost and Etheridge for all of these, and for some of them in this text. Initials across the top are for the families represented: CH, Chameleonidae (including agamids, etc.); CO, Corytophanidae (basiliscines); CR, Crotaphytidae (crotaphytines); H, Hoplocercidae (morunasaurs); Iguanidae (iguanines); Opluridae (oplurines); PH, Phrynosomatidae (sceloporines); PO, Polychridae (anolines); T, Tropiduridae (tropidurines).

Symbols in the table are as follows: +, present; –, absent; Q, quadrangular; D, domed; Y, Y-shaped; T, trapezoidal; V, variable; F, in frontal; I, in suture; M, medial; SH, short; L, long; IS, isolated and separated; C, confluent; A, acrodontan; P, primitive; S, S-shaped; ST, sink-trap; U, unicapitate and unisulcate.

mined that the many folds seen in *Amblyrhynchus* are homologous to the septa seen in other species. Iverson (1980) found only one septum present in all *Dipsosaurus*. The situation in *Sauromalus* is unresolved. Iverson (1980) found septa in all seven specimens he examined, but cites two sources for absence of septa in other individuals. Iverson (1980) found the number of septa to be variable individually (*Iguana delicatissima*), geographically (*I. iguana*), and ontogenetically (species not named by Iverson 1980: 88) within species.

Traditionally, a strong case has been made for separation of the Iguania into three families: Chameleonidae *sensu stricto* for chameleons, Agamidae, and Iguanidae. I have long questioned the

use or value of separating agamids from iguanids. There are two seemingly important distinctions: acrodont teeth and maxillae in contact posterior to premaxilla. Both are far more complex and equivocal than the simplistic characterization of Frost and Etheridge implies.

Frost and Etheridge considered only the dentition on the posterior portions of the maxilla and dentary. Thus they made a simple qualitative distinction between acrodont and pleurodont. This is misleading. New World forms and Malagasy oplurines have entirely pleurodont dentition, presenting a similar dental gestalt and, apparently, etiology. The situation in the Old World agamids is one of amazing diversity. I have given little consideration to intrageneric or individual variation, so in the listing that follows I will cite individual specimens so that others may verify or refute my claims.

A classic acrodont like *Phrynocephalus mystaceus* (MCZ 33996) has fully socketed teeth on dentaries, maxillae, and premaxilla. The gestalt is reminiscent of a bulldog, with incisiform, caniform, and carnassial teeth well differentiated. (In this case I confidently reject dental gestalt as evidence of relationship on grounds of convergent evolution.) *Draco volans* (MCZ 37829) is slightly less extreme, but all teeth are acrodont and socketed. In many agamids the standard pattern is pleurodont incisiform teeth on the premaxilla, followed by caniform teeth on the maxillae, and then acrodont teeth posteriorly on the maxillae and dentaries. For example, *Ceratophora stoddarti* (MCZ 39836), *Leiolepis belliana* (MCZ 43087), *Agama planiceps* (MCZ 30624), and *Goniocephalus bruinjii* (MCZ 54209) .

In many individuals pleurodont teeth extend posteriorly onto the maxillae: *Japalura dymondi* (MCZ 15852 and 16738, but MCZ 16739 has all acrodont teeth) and *Hydrosaurus pustulosus* (MCZ 43727). Some have pleurodont teeth on the anterior dentaries: *Calotes versicolor* (MCZ 44230-3) and *Amphibolurus barbatus* (MCZ 37200).

A subacrodont condition is common in agamines. Here the tooth is socketed but widely open on the lingual aspect, closely approaching the pleurodont condition: *Acanthosaura armata* (MCZ 39156: maxillae; premaxillary teeth are pleurodont), *Ceratophora stoddarti* (MCZ 39836, on anterior dentary), and *Calotes versicolor* (MCZ 44230-3, on the maxillae).

Other agamine dental conditions are bizarre. In *Moloch horridus* (MCZ 86751) all teeth are acrodont, but those on the maxillae are canted lingually—a unique condition in my experience among all vertebrates. In *Uromastix acanthinurus* (MCZ 27376) the premaxillary teeth are fused, *Sphenodon*-like, into a beak—in this case bluntly tricuspid. The remaining teeth are acrodont. In *Amphibolurus barbatus* (MCZ 37200) the premaxillary teeth are subacrodont, the anterior dentary teeth pleurodont, and the teeth on the posterior maxillae and dentaries fused into a cap-like ridge.

I have noted only some of the array of variation one may discern in these lizards. Simply put, dental characters provide a continuum from all pleurodont, through some pleurodont and some acrodont, to all acrodont, with some subacrodont, and with branches off to various sorts of heterodonty, fusions, and cantings. There are not two sorts of teeth and teeth do not provide any way to divide iguanians into acceptable families.

The meeting of the maxillae posterior to the premaxilla is arguably definitive only if one accepts a simplistic presence versus absence condition and ignores compromising variation. In New World forms, again, the situation is relatively simple: the premaxillary-vomer articulation is broad and the maxillae do not closely approach. In Old World forms the situation is again complex. In *Calotes versicolor* (MCZ 44230-3), for example, the maxillae meet but the junction varies from wider than the ventral aspect of the premaxilla (i.e., very broad) to barely touching. In *Physignathus cocincinus* (MCZ 43732) the maxillae extend mesially as narrow bars or straps and their union is about 25% of premaxillary width. In Madagascan *Oplurus quadrimaculatus* (MCZ 67946) the situation is very similar; the maxillary bar-like processes extend mesially behind the premaxilla but are separated by a cartilaginous area and fall just short of contact. I cannot agree to base a family on such a variable character.

In sum, I believe Frost and Etheridge went in exactly the wrong direction. For me, Iguania divides neatly and unequivocally into two families that are easily recognized by gestalt, supported by numerous trenchant characters, and are unequivocally monophyletic:

Iguanidae.—Lizards with fully developed, functional eyes and four limbs; feet of ordinary saurian configuration; a broad frontal shelf underlying nasals; dracomorph brain-stem morphology; *m. intercostalis* absent; clavicles, interclavicle, and ceratobranchials present.

Chameleonidae.—Lizards with fully developed, functional, turreted eyes and four limbs; feet zygodactyl; a broad frontal shelf underlying nasals; dracomorph brain-stem morphology; *m. intercostalis* absent; clavicles, interclavicle, and ceratobranchials absent.

Relationships within my Iguanidae *sensu lato*, as defined above, are unresolved. Well-defined, easily recognized, and certainly monophyletic subfamilies resist delimitation. The informal appelations such as "agamine," "anoline," "iguanine," and "sceloporine" that have served me well for three decades continue to suit me. I find no new information, clarification, or improvement deriving from the Frost and Etheridge attempt at formal fragmentation.

All this leads back to my original question "why?" If splitting the Iguania into nine small, difficult to recognize "families" does not benefit (in fact hinders) me—a field biologist with a great and direct need for highly communicable information about easily identified groups—then what good does it do? Who benefits? Here are 65 printed pages resulting in an unwieldy plethora of taxonomic fragments with no information gain whatsoever. This is typical of the splitting literature in systematics that I see. To determine who benefits from its publication we will have to consider the motives of the authors, the structure of institutionalized "science" in our society, and economic and political constraints and ambitions, carrots and sticks. Fascinating as all that would be, it is beyond the scope of this review.

TECHNIQUES

The Use Of Mouse Glue Traps To Capture Lizards

"Sticky traps" have long been employed by herpetologists as a means of assessing the diversity and relative abundance of potentially available arthropod prey (e.g., Ballinger 1977; Dunham 1978; Simon 1975). Improved models of such glue traps have been widely employed in household use for the capture of both insects and small rodents and, more recently, have been used with some success in the capture of reptiles, including *Gekko chinensis* on South China Sea islands (Lazell 1988), *Hemidactylus turcicus* in Baltimore, Maryland (Norden and Norden 1991), and *Boiga irregularis* in Guam (Fritts 1988). However, the use of glue trapping in faunal surveying and censusing has not been mentioned by recent comprehensive reviews of herpetofaunal sampling methods (Campbell and Christman 1982; Karns 1986; Simmons 1987). We here report on the successful use of such traps for the capture of tropical arboreal lizards.

We employed 10 cm x 20 cm Victor® mouse glue traps (Woodstream, Inc., P.O. Box 327, Lititz, Pennsylvania 17543, USA) in the course of a survey of the herpetofauna of the Isle of Pines, a small (150 km^2) island approximately 50 km south of the southern tip of the French island territory of New Caledonia, in the southwest Pacific. Traps were attached by mylar packing tape to the trunks of ten coastal forest trees at a height of approximately 1.5 m above ground. As many traps as necessary (usually 2-4) were used to encircle the trunks. Traps were set in the afternoon of 29 February 1992 and checked at approximately 2000 h and 800 h for three consecutive days. These traps yielded 38 specimens of the New Caledonian endemic gecko *Bavayia sauvagii*, with 19, 17, and 2 geckos obtained on successive nights. Significantly, no specimens of this species were collected by hand in the vicinity, despite intensive searching. Elsewhere in its range the species typically spends daylight hours under stones or bark and emerges at night to hunt on the trunks of trees (Bauer and DeVaney 1987). The forest floor in the site studied (Gite Kodjeue, Baie de Waa Mé) has a pavement of highly dissected coral, which provides especially effective protection for small secretive lizards and prevents the application of standard hand and pit trap collecting methods.

Entrapment occurs immediately after contact with the glue surface, near the edge of the trap first entered by the lizard. Thus, documentation of both the presence of particular hard-to-sample taxa, and also of the direction of lizard movement (from the ground up rather than the canopy down in the case of *Bavayia sauvagii*) is possible. Further, if checked regularly over the course of the night, glue traps may reveal peak periods of activity of trunk-active reptiles. Simultaneous sampling of potentially available arthropod prey is also possible. Although held fast by the glue, all lizards were easily removed without ill effect by rubbing corn oil on their bodies and slowly peeling them off of the traps. As this could be done *in situ*, the traps could be left in place and used over an extended period of time. Changes in the color and apparent tackiness over four days, however, suggest that traps should not be set for more than one week.

Glue traps were also successful in capturing two other arboreal species. One specimen of *Lioscincus nigrofasciolatum* was collected on the forest traps described above. A second specimen was obtained on a beach front *Casuarina* sp. In this case the skink had been observed basking during the day and a trap was placed at the entrance of the hollow in the trunk. When checked the next morning both the skink and a *Lepidodactylus lugubris* had been captured. Traps were also opportunistically employed in terrestrial situations. While, in general, these yielded few lizards, they resulted in the capture of the only specimen of *Nactus pelagicus* obtained in the survey. This specimen was collected under the edge of a pile of coconut fronds at the forest edge, suggesting that this species may also use the coral pavement as a daytime retreat. Ground-placed traps also yielded a single individual each of the locally abundant skinks *Caledoniscincus austrocaledonicus* and *Marmorosphax euryotis*, both of which were otherwise easily captured by hand or by rubber banding.

Under some conditions glue traps may also prove effective when used in place of conventional pit traps in conjunction with drift fencing. Such trap lines take only minutes to set up and may be especially useful where rocky substrate hinders excavation. Nonetheless, the danger of thermal stress in most open habitats and the likelihood of fouling of the traps by leaf litter, soil, or debris may limit the effectiveness of terrestrial glue trapping in general. In the shaded and thermally stable conditions of tropical forests, however, glue traps may be the collecting method of choice for trunk- and branch-active reptiles (although similar methods were not successful in a Bornean rainforest plot, H. K. Voris, pers. comm.). Glue traps are inexpensive (when purchased in bulk they can be obtained for approximately $0.75 per unit for the size trap used in this study) and are far more time effective than night spotting for collecting at least some gekkonid lizards. We strongly advocate the addition of glue traps to the arsenal of collecting equipment used by herpetologists engaged in the surveying or censusing of reptiles.

Acknowledgments.—We thank Tom Fritts for providing ordering information and suggesting the use of corn oil to remove lizards from the traps and Joe Pilcicki for his continued service as a procurer of collecting supplies. Skip Lazell and Daryl Karns provided useful comments on the manuscript and Harold Voris provided information regarding the use of "rat glue" in Sabah.

A Device For Separating Fecal Samples Of A Mollusc-Feeding Turtle, *Malaclemys terrapin*

Studies of chelonian food habits have employed five primary techniques for dietary analysis: (l) laboratory feeding trials, (2) field observation, (3) dissection of the digestive tract, (4) stomach flushing, and (5) fecal analysis. Each method possesses unique advantages and the method selected depends upon the nature of the study or the need for repeated sampling (Graham 1979; Korschgen 1971; Legler 1977; Parmenter and Avery 1990). We used the nondestructive technique of fecal analysis to examine the dietary preference of an estuarine turtle, the diamondback terrapin *(Malaclemys terrapin)*. As the animals belonged to a demographic study of wild terrapins, there were concerns about preventing losses to the population. Fecal analysis was chosen as the preferred analytic technique because it is less invasive than stomach-pumping and does not involve sacrificing individuals from the population. We were able to address a disadvantage of this method indicated by Folkerts (1968) who noted that prey items that leave no trace in the feces are overlooked, meaningful volumetric analysis is precluded, and fecal remains often are difficult to identify. Concerned with these drawbacks, we developed an efficient method to separate fecal material, found that fecal remains from *Malaclemys* could be easily identified and prey size distribution quantified.

The diamondback terrapin is the only North American emydid of widespread occurrence in saltmarshes (Carr 1952; Ernst and Barbour 1989). Although terrapins principally feed on marsh-dwelling snails and crabs (Carr 1952), their functional role as macro-consumers has been largely overlooked for temperate salt marsh ecosystems (Pomeroy and Wiegert 1981). All studies of terrapin diet (reviewed by Palmer and Cordes 1988) concluded that the most important dietary item was snails. However, no studies to date have examined the size distribution of food items ingested by wild terrapins. To investigate the food habits of terrapins, we used a winnowing device to separate fecal samples into components based on similar mass.

Our study was part of an investigation to define the ecology of terrapins near a South Carolina barrier island (Lovich and Gibbons 1990; Lovich et al. 1991). From the intertidal saltmarsh west of Kiawah Island, we collected 294 terrapins using trammel nets and seines from 22 June to 27 July 1991. Fecal samples were collected for 21–48 h post-capture during temporary confinement in fiberglass holding bins (80 x 45 x 45 cm). Fecal materials were washed into U.S. Standard Testing sieves (#18 = 1 mm) and air dried for 24-48 h.

The samples consisted of snail shell fragments *(Littorina irrorata)*, intact snail opercula *(L. irrorata)*, and fragments of crab exoskeleton *(Uca* spp., *Calinectes sapidus, Sesarma* spp.). *Littorina* was both numerically and volumetrically (minimum estimate of 90%) the most significant prey item. A linear regression of opercula length (x) to snail length (y) was generated from measurements spanning all size classes of *Littorina* in the area ($y = 2.9 x - 1.1$, $r^2 = 0.90$, $n = 270$, $p = 0.001$). The positive relationship allowed us to reconstruct the size range of snails ingested from intact opercula in the fecal sample. However, the analysis was impeded by the difficulty of sorting out the small snail opercula (2-8 mm diam).

We constructed a winnowing apparatus to facilitate the separation of opercula from the heavier portions of the sample (crab legs, shell fragments, sediment) (Fig. l). Dried fecal material was carefully loosened from the bottom of the sieve (S) and a large inverted funnel (F) was fitted closely over the upper rim of the sieve to cap it, forming the lower chamber. The funnel's spout was directed upwards with a nylon mesh (M) surrounding the spout. The spout was inserted through a 3 cm slit incised in the bottom of a mesh jelly strainer and secured with a rubber band [RB]). An inverted 500 ml beaker (B) was held a short distance above the funnel spout. The nylon mesh was secured around the lip of the beaker with another rubber band. A stream of air provided by a small hair dryer (HD) was directed upwards through the sieve. A support for this device can be made from 1/4" plywood, threaded rod, and nuts to lend stability for one individual to winnow a sample unassisted.

The principle of winnowing is to separate items by their relative mass. To operate the winnowing device, the air jet is aimed at the bottom of the sieve to suspend or propel fecal particles of different mass. Lighter particles suspended by the air jet are directed through the funnel into the upper chamber while heavier particles remain in the lower chamber. Particles in the upper chamber are deflected downwards after hitting the beaker and accumulate in the nylon mesh surrounding the funnel spout. By changing the distance of the beaker above the funnel, the capture efficiency of the upper chamber is varied. When the sample has been winnowed sufficiently to separate particles of similar mass, the sieve is removed and the upper chamber is inverted. The particles

contained by the mesh are carefully shaken into the beaker. Distinct sequential separations by mass are achieved by progressively moving the air source closer to the sieve. The time necessary to separate a sample declines from about 1 h for manual sorting to < 5 min when winnowing.

This apparatus is useful in dietary studies of animals that leave recognizable fecal remains as evidence of dietary preference. The analysis is ideally suited to dietary specialists that concentrate upon molluscs or gastropods, e.g., *Graptemys, Kinosternon, Macroclemys, Malaclemys, Malayemys,* and adult *Sternotherus* are all noted to feed extensively upon snails (Ernst and Barbour 1989; Folkerts 1968). Ingestion of plant tissue or soft foods by chelonians might be underestimated by the technique since this material is not easily identified.

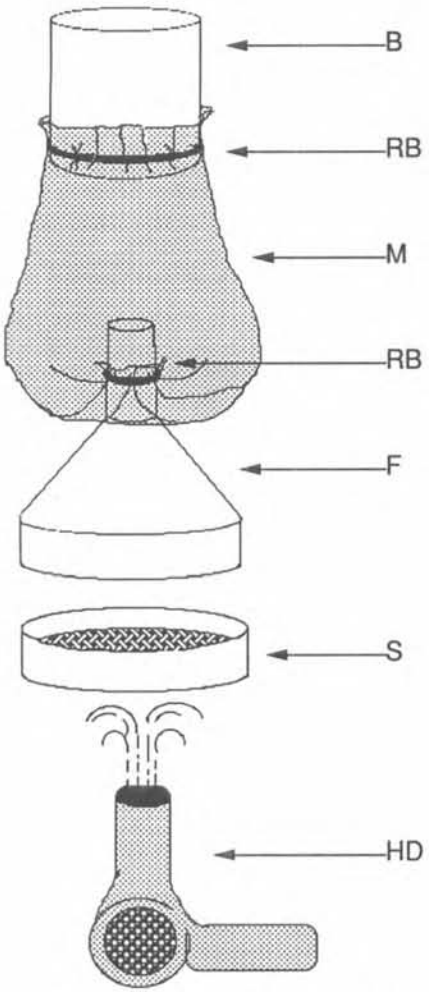

FIG. 1. A winnowing apparatus for separation of dietary components from fecal samples of mollusc-feeding turtles. Components include: beaker (B), fine mesh (M), rubber bands (RB), a funnel (F), a #18 mesh sieve (S), and a hair-dryer (HD).

The method may also provide an approach to investigate size-related resource partitioning, particularly in sexually dimorphic species such as *Graptemys barbouri, Graptemys pulchra,* and *Malaclemys terrapin* (Ernst and Barbour 1989; Gibbons and Lovich 1990; Vogt 1981). In those species, resource partitioning may serve as a driving force in the evolution of sexual dimorphism (Camilleri and Shine 1990; Shine 1989) to reduce intraspecific competition. If a relationship exists between body size and food size selectivity (Schoener 1974), it may be overlooked if dietary components are analyzed solely on a volumetric or numerical basis rather than a size specific basis. With the aid of a winnowing apparatus data will better indicate the extent of niche overlap, either between sexes and size classes or interspecifically, if multiple species are being compared. The technique is particularly useful to estimate the magnitude and selectivity of predation by snail-feeding specialists.

Acknowledgments.—A field grant from Earthwatch Expeditions, Inc. provided volunteer support for most of the field collecting. We thank H. Solovei for design refinements, B. Willis for separating samples, and T. Zimmerman for help with field studies. Summer students and the herpetology group at the Savannah River Ecology Laboratory helped with seining turtles and measuring opercula. W. Gibbons and J. Lovich provided helpful criticism of an earlier manuscript draft. Dock access was permitted by the Kiawah Island Community Association. Manuscript preparation was supported by contract number DE-AC09-76R00-8 19 between the U.S. Department of Energy and the University of Georgia's Savannah River Ecology Laboratory.

LIFE HISTORY NOTES

Instructions for contributors to Life History Notes appear in volume 23, number 2.

CAUDATA

NOTOTRITON BARBOURI (NCN). **REPRODUCTION**. On the night of 7 August 1991 on the east slope of Pico Pijol, Departamento de Yoro, Honduras, at 1920 m, we found a single clutch of five adherent, non-stranded salamander eggs (KU 219991) within the moist walls of an abandoned hummingbird nest. The bird nest was suspended from a limb of a broadleaf tree about 2 m above the ground. No adult salamander was attending the eggs. On the morning of 9 August 1991, at 1930 m at the same locality, a partial examination of another abandoned hummingbird nest found under similar conditions revealed another clutch of salamander eggs and an adult *Nototriton barbouri* (KU 219990). The salamander was in a coiled position, although not coiled around any eggs, and was near and in partial contact by its tail with a single clutch of salamander eggs. The bird nest was then carefully reconstructed and secured inside a cloth collecting bag and suspended from the same limb on which it was found. On the following morning, the salamander was found to be in the same position and place within the bird nest as the previous day, but was now coiled around six eggs (KU 219996) obviously deposited since the previous morning (Fig. 1). An examination of the remainder of the bird nest revealed four clutches of salamander eggs (KU 219992-95) in addition to the newly deposited clutch. The eggs in each of these five clutches were adherent and non-stranded, clutch size ranged from 6-19 ($\bar{x}$ = 10.8). Two of the communal clutches (KU 219992, 219995) contained late embryos with reduced gills and were well-pigmented and had well-developed feet and toes. We identified these embryos as *N. barbouri* based on the pigmentation and the long, slender, weakly-webbed toes. The two other advanced communal clutches had pigmented embryos with well-developed limb buds with poorly developed feet. The solitary clutch was similar in development to the most advanced embryos and obviously conspecific. Average egg capsule diameter of the six clutches ranged from 4.7 to 5.2 mm.

Attendance of egg clutches, usually by the female, is widespread within the Plethodontidae and is thought to be essential to clutch survival (Hom et al. 1990. Herpetologica 46:304-319). Vial (1968. Revista Biologia Tropical 15:13-115) found that egg clutches of *Bolitoglossa subpalmata* ceased development and died if abandoned by the attending adult. Nussbaum (1985. Misc. Publ. Mus. Zool. Univ. Michigan 169:1-50) listed 13 species of neotropical bolitoglossines in which egg attendance is known. Adult egg attendance has also been reported in five other neotropical bolitoglossines (*B. diminuta*: Robinson 1976. Proc. Biol. Soc. Washington 89:289-294; *B. platydactyla*: Smith et al. 1968. Herpetologica 24:67-72; *B. yucatana*: Barbour and Cole 1906. Bull. Mus. Comp. Zool., Harvard 50:146-159; *Lineatriton lineola*: Sessions 1977. Herpetologica 33:452-454; *Pseudoeurycea expectata*: Stuart 1954. Proc. Biol. Soc. Washington 67:159-178). Duellman (1961. Univ. Kansas Publ. Mus. Nat. Hist. 15:1-148) did not mention attendance with four egg clutches of *P. belli*. It is perhaps noteworthy that one of these clutches "...was partially dessicated" and another "... was being eaten by beetles ..." (Duellman 1961:17). The only other record of non-attendance in a neotropical bolitoglossine of which we are aware is that of *B. compacta* (Hanken 1979. Copeia 1979:741-744) from eggs deposited in captivity. This may have resulted from behavior brought on by captivity.

The fact that five healthy, advanced clutches of *N. barbouri* were found without an attending adult strongly suggests that egg brooding does not occur in this species. Vial (*op. cit.*) noted that in captivity brooding adults of *B. subpalmata* seldom left the eggs, doing so only for short periods of time apparently to forage for food. Adults of *N. barbouri* were commonly seen at night on Pico Pijol while apparently foraging on limbs and branches of small trees and shrubs. None were found active at daylight hours at which time four of the five advanced clutches were found, thus it is extremely unlikely that the adults were temporarily away from all five clutches. Oviposition by *N. barbouri* resembles that of the western North American bolitoglossine *Batrachoseps attenuatus*, which often deposits eggs in communal nests (Maslin 1939. Copeia 1939:209-212) that are often not attended by adults (Maiorana 1976. Evolution 30:599-613). The eggs of both these species also develop during the rainy season, opposite of the pattern for most neotropical bolitoglossines (Houck 1977. *In:* Taylor and Guttman [eds.]. The Reproductive Biology of Amphibians. Plenum Press, New York: pp. 43-72), suggesting that egg brooding in these species may serve in part to keep the eggs moist during long periods of little or no rainfall. On the other hand, egg brooding to keep the eggs moist would not be necessary for rainy season developing *N. barbouri* if the female chooses a satisfactory site for egg laying. Maiorana (1976, *op. cit.*) made a similar suggestion for the non-brooding *B. attenuatus*.

FIG. 1. Adult *Nototriton barbouri* with multiple clutches of eggs.

TESTUDINES

CARETTA CARETTA (Loggerhead). **PELAGIC MOVEMENT AND GROWTH**. This note reports the first confirmed movement of a non-headstarted *Caretta caretta* from the Atlantic into the Mediterranean Sea. The turtle was one of over 1200 sea turtles tagged in the waters around the Azores in a joint project of the University of Florida, USA, and the University of the Azores, Portugal. The turtle was tagged with a monel metal tag (style #681, National Band and Tag, Newport, Kentucky) on 14 July 1986, 80 km east of the island of Flores, Azores. Straight carapace length from center of nuchal scute to distal tip of the posterior marginal (SCL) was 17.0 cm. The turtle was recaptured on a drifting longline set for swordfish on 26 August 1991, 43 km from Licata, Agrigento, Sicily. Curved carapace length from center of nuchal scute to distal tip of the posterior marginal (CCL) was 42 cm. The turtle was observed by personnel of Porgetto Tartarughe, Italy, and released alive.

CCL (42 cm) was converted to SCL (36 cm) using the equation in Frazer and Ehrhart (1983. Marine Turtle Newsl. 24:4-5) and unpublished data (Bolten and Martins) for smaller class sizes. Thus, the turtle grew at a rate of 3.7 cm/yr during the 61-mo interval. This is the first reported growth increment for a non-headstarted pelagic-stage sea turtle and is much slower than reported for similar-sized loggerheads in benthic habitat in the southern Bahamas (Bjorndal and Bolter 1988. J. Herpetol. 22:480-482). The von Bertalanffy and logistic models presented for Florida loggerheads by Frazer and Ehrhart (1985. Copeia 1985:73-79) predict growth rates of 8.1 cm/yr and 2.6 cm/yr, respectively, for the same size interval. Our value is closer to that predicted by the logistic equation. Although the von Bertalanffy model has a better fit for growth of sea turtles on benthic foraging grounds, this model may not fit data for growth rates in the very different pelagic habitat (Bjorndal and Bolten 1988. Copeia 1988:555-564). Greater knowledge of growth in the pelagic habitat is critical for demographic studies.

The extent of movements of sea turtles into the Mediterranean is important for the development of management plans for the region. Large numbers of juvenile loggerheads are caught each year incidental to the long-line fisheries. Whether this take is supported entirely by juveniles from the declining Mediterranean nesting populations or is supplemented by the larger turtle populations in the Atlantic, has important implications for the survival outlook of the Mediterranean *Caretta* populations.

Other sea turtles that apparently move from the Atlantic to the Mediterranean include *Lepidochelys kempi* (Brongersma and Carr 1983. Proc. Koninklijke Nederlandse Akademie van Wetenschappen, C 86:445-454) and *Dermochelys coriacea* (Groombridge 1990. Marine turtles in the Mediterranean: distribution, population status, conservation. Council of Europe, Nat. and Environ. Ser. 48). Also, a headstarted *C. caretta* (raised in captivity for about a year before release off Padre Island, Texas, USA) has been recaptured in the Mediterranean (Manzella et al. 1988. Marine Turtle Newsl. 42:7). However, headstarted turtles often end up in unnatural sites (Taube 1992. Science 256:614-616), so their movements must be interpreted with caution.

We thank C. K. Dodd and C. J. Lagueux for their assistance. This work is supported by the Marine Entanglement Research Program of the U.S. National Marine Fisheries Service.

CLEMMYS INSCULPTA (Wood Turtle). **SIZE**. On 21 May 1984, an adult male *Clemmys insculpta* (RAS-251) was captured in Pontiac Co., Quebec. Measurements were CL=238 mm; PL=207mm; PW=109 mm. This specimen is presently being maintained by the author.

On 15 June 1985, another adult male was captured in the same area. Its measurements were CL=234.5 mm; CW=161.8 mm; PL=210.2 mm; PW=109.1 mm. This specimen was deposited at the Canadian Museum of Nature (NMC 26568). All measurements were taken by Dr. F. R. Cook, Curator of Herpetology, CMN. The first specimen exceeds and the second is equal to the maximum carapace length reported in Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.) as 234 mm for this species.

Submitted by **RAYMOND A. SAUMURE**, 169 D'Auvergne Ave., Gatineau, Quebec, J8T 1J5, Canada.

STERNOTHERUS ODORATUS (Stinkpot). **REPRODUCTION**. *Sternotherus odoratus* is reported to mate under water in the shallows of lakes at night or in the early morning hours (Ernst and Barbour 1989. Turtles of the World, Smithsonian Institution Press, Washington, D.C. 313 pp.). Mating adults have been observed to congregate, with up to thirty specimens being collected within a radius of 15 ft (Risley 1933. Pap. Michigan Acad. Sci., Arts Letters 17:685-711). Ernst and Barbour (*op. cit.*) stated that mating occurs throughout the year, with peaks in the spring and fall, and Carr (1952. Handbook of Turtles, Cornell Univ. Press, Ithaca, New York, 542 pp.) stated that copulation occurs from April until as late as October. Ernst (1989. J. Herpetol. 20(3):341-352), however, observed mating only from 15 April to 22 May. Here, we describe a pair of *S. odoratus* mating on land, late in the year, and in mid-afternoon.

On 15 October 1989 at 1500 h, at Crab Orchard Lake, Williamson Co., Illinois, we observed a pair of *S. odoratus* mating on the former lake bed in a partially isolated cove 0.2 km north of the west side boat launch (the water level of the lake had been lowered 1.3 m for renovations of the dam). The male had mounted the female when the turtles were first noticed. The female (CL=105.1 mm) was just out of the water with her posterior end near the water's edge, and the male's (CL=100.7 mm) hind legs were in the water. Ernst (*op. cit.*) described 12 pairs of mating *S. odoratus* and the male was always larger than the female. We collected, sexed, and released five other *S. odoratus* (three males, two females) in the shallows less than five meters away from the mating pair.

We thank Crab Orchard National Wildlife Refuge for allowing us to work there; Wendall Crews for his help in obtaining the necessary permit; and Ronald A. Brandon and John L. Carr for their critical review of this manuscript.

SAURIA

ANOLIS GINGIVINUS (NCN). **NOCTURNAL ACTIVITY**. Schwartz and Henderson (1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville, xvi + 720 pp.) reported nocturnal activity on or around structures for three Antillean anoles: *A. bimaculatus* (Antigua), *A. cristatellus* (Puerto Rico and the Dominican Republic) and *A. sagrei* (Bahamas). Similar observations have been made by RWH of *A. marmoratus* (Guadeloupe) and *A. sabanus* (Saba). The anoles were associated with hotels in all instances. During the week of 16–23 May 1992, five *Anolis gingivinus* were repeatedly observed by RP foraging for insects around lights on walls or on lamp posts as late as 2300 h in the Pelican Resort Complex at Simpson Baai, St. Maarten. In one instance, two individuals were active around the same light. All the lizards were subadult males. On the night of 20 May, a *Hemidactylus mabouia* was taken from a lamp post in the complex. The following night a sixth subadult male *A. gingivinus* was observed on the perch previously used by the gecko. These individuals were unusually sensitive to human disturbance at night, retreating into vegetation upon approach by an observer within <3 m. During the day, these lizards (although possibly not the same individuals) could easily be approached to within <25 cm.

BARISIA IMBRICATA IMBRICATA (NCN). **PREDATION**. *Barisia imbricata imbricata* is an anguid lizard distributed in the Mexican Transvolcanic Belt (mountains of Distrito Federal, Hidalgo, Jalisco, México, Michoacan, Morelos, Oaxaca, Puebla, and Veracruz), and occurs at high elevations (2100-4000 m) in coniferous or pine-oak forest (Guillette and Smith 1982. Trans. Kansas Acad. Sci. 85:13-33). Few accounts of the biology of this species exist. Duellman (1961. Univ. Kansas Publ. Mus. Nat. Hist. 15:1-148) reported predation on *B. i. imbricata* by *Crotalus pusillus*, Guillette and Smith (*op. cit.*) reported distributional records, and Guillette and Casas-Andreu (1987. Herpetologica 43(1):29-38) studied its reproductive cycle. Here we report additional habitat descriptions and reptilian predators of this lizard.

On 7 June 1991, while observing *Sceloporus mucronatus* near km 24.5 on the Ajusco-Tianguistenco highway (Mexico Hwy 892, Distrito Federal), we captured a *Thamnophis scalaris* (wet body mass = 97 g). During handling, the snake regurgitated a partially digested adult *B. i. imbricata* (ca. 85 mm SVL). During early August, individual *S. mucronatus* were collected for stomach analyses. One male (JLE00040, SVL = 91 mm, wet body mass = 33 g) contained a young *B. i. imbricata* (ca. 45 mm SVL). *Barisia i. imbricata* is a common anguid lizard at this site. Most observations (n = 21) of this lizard were in grasses (*Festuca amolisima*) where *T. scalaris* was also observed (n = 2). *Barisia i. imbricata* was also observed on basaltic rocks and lava (n = 3) where *S. mucronatus* occurs. Another potential predator observed syntopically with *B. i. imbricata* is *Crotalus triseriatus*. This rattlesnake was also common in grasses (n = 17). These observations increase the number of predatory species of *B. i. imbricata* to include another lizard and at least one snake.

The preserved specimen (JLE00040) will be deposited in the vertebrate collection of Instituto Nacional de Investigaciones Forestales y Agropecuarias de México (Accession INIFAP#). A permit (412.2.1.2.0.06869 Direccion General de Conservacion Ecological de los Recursos Naturales) to collect specimens for research was kindly granted by Dr. Graciela de la Garza Garcia. John Rowe and Geoff Smith provided useful comments on an early draft of this manuscript. This research was supported by Instituto Nacional de Investigaciones Forestales y Agropecuarios de México (INIFAP), and Consejo Nacional de Ciencia y Tecnologia de México.

GAMBELIA SILA. (Blunt-nosed Leopard Lizard). **REPRODUCTION**. The number of young that a female produces in her lifetime is an important life-history trait that affects her fitness. The number of eggs produced by oviparous lizards can be affected by the age, size, and physiological condition of the individual. Multiple clutches of eggs in a year is one way a female can increase her output beyond the physical limitations of her size.

From late April to the middle of July, 1992, we found several female *Gambelia sila* that produced two to four clutches of eggs at our permanent study plots on the Elkhorn Plain, San Luis Obispo County, California. Egg number and relative size can be accurately determined by palpation. We captured each female by pole and noose as often as found on a plot, and weighed each individual to the nearest 1 g using a 100 g Pesola scale. Leopard lizards deposit the entire clutch at one time (Montanucci 1967. Herpetologica 23:119-125), so we inferred that multiple clutches of eggs had been produced by changes in egg number and/or mass over a period of eleven weeks.

Changes indicative of production of at least a second clutch were seen in six females: number 18 (102 mm SVL) - 4 eggs, 38 g on 27 April to 3 small eggs, 36 g on 15 June; number 27 (107 mm SVL) - 3 eggs, 36 g on 1 May to 4 eggs, 30 g on 20 June; number 12 (117 mm SVL) - 5 eggs, 62 g on 6 May to 3 medium-sized eggs, 44 g on 22 June; number 18-2 (105 mm SVL) - 5 eggs, 42 g on 7 May to 4 eggs, 37 g on 19 May; number 16 (99 mm SVL) - 3 eggs, 31 g on 8 May to 0 eggs, 24 g on 22 May to 3 medium-sized eggs, 35 g on 19 June; number 31 (114 mm SVL) - 5 eggs, 55 g on 8 May to 3 eggs, 49 g on 23 June.

Changes indicative of production of at least a third clutch were seen in 3 females: number 13 (112 mm SVL) - 4 eggs, 46 g on 4 May to 5 small eggs, 44 g on 18 May to 4 medium-sized eggs, 44 g on 4 June; number 4 (104 mm SVL) - 2 eggs, 35 g on 8 May to 3 small eggs, 32 g on 18 May to 4 small eggs, 31 g on 23 June; number 6 (117 mm SVL) - 5 eggs, 56 g on 19 May to 3 medium-sized eggs, 45 g on 28 May to 4 medium-sized eggs, 41 g on 26 June.

Four clutches of eggs were seen in one female (112 mm SVL): 5 eggs, 50 g on 1 May to 4 eggs, 46 g on 15 May to 4 medium-sized eggs, 46 g on 16 June to 3 eggs, 45 g on 14 July. No data exist for the length of time eggs remain in the oviduct before oviposition.

Multiple clutches in *G. sila* have been suspected but not positively determined (Montanucci 1965. Herpetologica 21:270-283; Tollestrup 1982. Am. Midl. Nat. 108:1-20; Germano, Williams, and Tordoff, ms. in review). These are the first data that confirm the production of multiple clutches in *G. sila*. We also found a female (118 mm SVL, 58 g) carrying six eggs on 27 April. This is only the

second report of six eggs carried by *G. sila* (Montanucci 1970. Copeia 1970:104-123).

MICROLOPHUS BILINEATUS (Galápagos Lava Lizard). **MORPHOLOGY**. A bifid-tailed adult male *Microlophus bilineatus* (Fig. 1) was observed on 28 May 1990 on San Cristobal, Galápagos, inhabiting a rock pile near the harbor. The animal was not captured for closer inspection. However, it was noted that the bifurcation occurred ca. 20-30 mm from the vent with the left branch of the tail originating ca. 5 mm anterior to the point of regeneration of the right branch. Reports of bifid- and even trifid-tailed lizards are relatively common in the literature (Scott 1982, Herpetol. Rev. 13(2):46). However, apparently this is the first report for *M. bilineatus*.

FIG. 1. Bifid-tailed *Microlophus bilineatus*.

SERPENTES

CROTALUS ADAMANTEUS (Eastern Diamondback Rattlesnake). **BEHAVIOR**. Many aspects of the life history of *Crotalus adamanteus* are not well known, and few observations have been documented. It has been suspected that this species may utilize the same refuge during consecutive seasons, but review of the literature did not reveal any reference to verify this behavior. This report describes the use of a refuge by *C. adamanteus* during three consecutive seasons.

On 17 March 1989, a juvenile male *C. adamanteus*, 60 cm TL, was observed in Jasper Co., South Carolina. The individual was found coiled in the entrance of a tunnel at the base of a decayed tree stump. The animal was sexed, measured, photographed for identification, and released. Sketches detailing head pattern were also recorded for identification. The location of this refuge was noted and the site was marked with a colored ribbon affixed to vegetation.

On 7 February 1990, this individual was again observed at the entrance to this refuge. Comparisons of photographs and head sketches verified identity. During the preceding eleven months, TL had increased by 16 cm, to 86 cm. At this time, a 1.5 x 0.5 cm red plastic tag, designed for marking fish, was attached to the basal rattle segment using monofilament line. This tag contained an individual identification number and an address for return of the tag in the event the snake was captured or killed.

On 10 May 1991, the specimen was observed for the third time at the site. The identification tag was still in place. Length had increased 23 cm during the preceding sixteen months to 109 cm TL. Unfortunately, no attempt was made to locate this animal during 1992.

ELAPHE VULPINA (Fox Snake). **PREDATION**. On 20 April 1992, I observed a juvenile red-tailed hawk, *Buteo jamaicensis*, feeding on a snake while perched on a fence post along State Hwy. 41 in eastern Brown Co., Wisconsin (T22N, R19E, S16). The bird was startled by an oncoming truck and flew off, dropping the snake a short distance from the fence post. I examined the snake and identified it as *Elaphe vulpina* (ca. 1 m TL). It had several lacerations (1-3 cm long) on its sides, and the liver had been almost completely excised. The hawk reclaimed the snake after I left the site.

The only raptors previously reported to prey on *E. vulpina* are the bald eagle, *Haliaeatus leucocephalus* (Pierce and Ross 1989. Passenger Pigeon 51:155-156) and the northern goshawk, *Accipiter gentilis* (Zirrer 1947. Passenger Pigeon 9:79-94). However, *E. vulpina* is probably a common prey item of raptors. Ross (1989. Amphibians and reptiles in the diets of North American raptors. Wisconsin Endangered Resour. Rept. 59:1-33. Wisconsin Dept. Natur. Resour., Madison) documented the occurrence of amphibians and reptiles in raptor diets, including several other colubrids in the diet of *B. jamaicensis*.

That the hawk fed first on the liver is similar to observations of common crows, *Corvus brachyrhynchos*, which catch *Thamnophis sirtalis* and feed only on their livers (Aleksiuk 1975. Natl. Geog. 152:715-723).

Submitted by **DREUX J. WATERMOLEN**, Water Resources Management, Wisconsin Department of Natural Resources, P.O. Box 10448, Green Bay, Wisconsin 54307-0448, USA.

HYPSIGLENA TORQUATA (Night Snake). **PREDATION**. Predation on lizards by scorpions is well-documented (McCormick and Polis 1982. Biol. Rev. 57:29-58). *Leptotyphlops humilis* commonly falls prey to several species of scorpions, including *Hadrurus arizonensis* and the sand scorpion *Paruroctonus mesaensis*, but predation by scorpions on other snakes is not well-documented (Polis 1979. J. Zool., London 188:393-346; McCormick and Polis, *op. cit.*). This observation represents the first record of predation on *Hypsiglena torquata* by a scorpion and the first record of the scorpion *Diplocentrus bigbendensis* preying upon a snake.

FIG. 1. The scorpion *Diplocentrus bigbendensis* feeding on *Hypsiglena torquata*. (Photo by Terry Hibbitts).

On the morning of 8 June 1989, at ca. 0230 h, an adult *D. bigbendensis* was found feeding on a dead *H. torquata* 27.4 km west of Lajitas on Ranch Road 170, Presidio Co., Texas, at ca. 830 m elevation on the southern slopes of Santana Mesa, a large hill covered with igneous boulders interspersed with bare, rocky soil. The air temperature was 30°C. The scorpion and snake were found by Tony Hibbitts in an area of bare soil between boulders. The snake was ca. 300 mm TL, while the scorpion was ca. 45 mm, not including the metasoma. The scorpion was found motionless with the snake grasped in its chelicerae, feeding from a small laceration ca. 40 mm behind the snake's head (Fig. 1). No other lacerations were evident on the body of the snake. Both *H. torquata* and *D. bigbendensis* are common in this area.

I thank Kelly Hogan and Thomas E. Lee, whose suggestions were helpful in editing a previous version of this manuscript.

Submitted by **TROY HIBBITTS**, Department of Biological Sciences, University of Texas at Arlington, Arlington, Texas 76019, USA.

LAMPROPELTIS TRIANGULUM SMITHI (NCN). **SIZE**. The maximum reported TL for female *Lampropeltis triangulum smithi* is 973 mm (Williams 1988. Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*. Second ed. Milwaukee Publ. Mus. x +176 pp.).

On 29 March 1991, an adult female *L. t. smithi* (MZFC 05025: 863 mm SVL, 1006 mm TL) was collected by Mario Mancilla in a site with secondary vegetation near Nonoalco, Hidalgo, México, at an elevation of 1680 m. This snake is 33 mm longer than Williams' (*op. cit.*) longest female specimen, although he reported males reaching a TL of 1138 mm. TL of four male *L. t. smithi* in MZFC (030, 0484, 05024, and 05026) are 275 mm, 378 mm, 420 mm, and 969 mm, respectively.

We thank Arturo González, H. Smith, Mario Mancilla M., Oscar Flores V., and Adolfo Navarro S. for their assistance on this manuscript and their assistance with the field work. O. Flores provided helpful information. Funding was provided by the Dirección General de Apoyo al Personal Académico (DGAPA) project IN201789.

RHADINEA BILINEATA (NCN). **DIET.** Snakes of the arboreal and frog-eating genus *Leptodeira* are well-known for feeding on arboreal frog eggs (Duellman and Trueb 1986. Biology of Amphibians, McGraw-Hill, New York, 670 pp.). Instances of frog oophagy in terrestrial snakes, such as that recorded for *Liophis atraventer* (Dixon and Thomas 1985. Herpetologica 41:257-262), seem less common. The feeding habits of South American species of the large genus *Rhadinea* are poorly known, although lizards and frogs are recorded as food of the widespread *R. brevirostris* and *R. occipitalis* (Cunha and Nascimento 1978. Publ. Avuls. Mus. Para. Emilio Goeldi 10:1-218). Here, we report on frog oophagy by *R. bilineata*, a species endemic to southeastern Brazil whose habits are little known (Di-Bernardo and Lema 1990. Acta Biol. Leopoldensia 12:359-391). Fieldwork was done at the Parque Estadual in Campos do Jordão, São Paulo, southeastern Brazil (ca. 22°45'S, 45°34'W, 1550 m) in montane, *Araucaria* and *Podocarpus* rainforest during the wet season from January to March 1992.

Four specimens of *R. bilineata* (housed in ZUEC, Leviton et al. 1985. Copeia 1985:802-832) were caught while moving on the ground in forest trails in early morning (n=1) and late afternoon (n=3). We observed two additional snakes crawling amidst roots and creeping vegetation on stream banks in middle afternoon. Thus *R. bilineata* is diurnal and exhibits cryptozoic habits when presumably foraging. One specimen caught at 1630 h had 24 recently ingested frog eggs in its gut. The eggs were identified as those of *Eleutherodactylus*, a forest floor frog genus with terrestrial

eggs and direct development (Duellman and Trueb, *op. cit.*). All the eggs were at a similar developmental stage (close to hatching, see Figs. 6-8 in Lynn and Lutz 1946. Bol. Mus. Nac. Rio de Janeiro, Zool. 71:1-46), so probably were from a single clutch. The small size (ca. 50 cm TL), elongated head, and slender body of *R. bilineata* appear well-suited for foraging on small frogs and their terrestrial eggs sheltered in crevices and holes on forest floor and stream banks. As several tropical frogs present terrestrial eggs (Duellman and Trueb, *op. cit.*) it is tempting to speculate that frog oophagy will be found among other small, frog-eating snakes with cryptozoic foraging habits.

We thank M. J. Robim (Instituto Florestal) for logistical support, O. Augusto for help in fieldwork, M. Di-Bernardo (snakes) and J. P. Pombal-Jr. (frog eggs) for confirmation of our identifications, and the CNPq for financial support.

Submitted by **IVAN SAZIMA, SAMIRA A. CHINI**, and **CELSO R. C. SOUZA**, Departamento de Zoologia, Universidade Estadual de Campinas, 13081-970 Campinas, São Paulo, Brasil.

TRIMORPHODON BISCUTATUS (Lyre Snake). **PREY**. Oliver (1937. Occas. Pap. Mus. Zool. Univ. Michigan 360:1-30), Alvarez del Toro (1982. Los Reptiles de Chiapas, 3rd ed., Tuxtla Gutiérrez, Chiapas, Gobierno de Estado, México, Publicación del Instituto de Historia Natural, 247 pp.) and Stebbins (1985. A Field Guide to Western Reptiles and Amphibians, Houghton Mifflin Co., Boston, Massachusetts, 336 pp.) reported that prey of *Trimorphodon biscutatus* included small lizards, birds, and bats. Recent observations of this snake from Chamela, Jalisco, revealed the diet to include the small nocturnal lizards *Phyllodactylus lanei rupinus* and *Hemidactylus frenatus* (A. Ramírez-Bautista, unpubl. data), and *Ctenosaura pectinata* (Ramírez-Bautista and Uribe 1992. Herpetol. Rev. 23:82). In this report, we add bats to the prey of *T. biscutatus* in Jalisco.

Our observations were made in a culvert located at about km 59.1 under Highway 200 in a tropical deciduous forest and near the Biological Field Station, Chamela, Jalisco, México from 1979 to 1990. Each year from July to September a maternity colony of the bat *Natalus stramineus saturatus* occurs in the culvert. The culvert is oriented east to west and is about 20 m long and 1.2 m diam. Mean temperature in the culvert was 28°C (25-31°C) during July and August.

Over twelve years, we observed 11 *T. biscutatus* in the culvert, and two of the snakes were observed eating young bats. Each snake ate one bat. Snout-vent lengths of the two snakes were 1300 and 1200 mm, and total lengths of neonate bats were 59.0 and 63.5 mm respectively. In both cases the snakes climbed the wall of the culvert on a straight line and moved toward the groups of bat pups with the head retracted. Each young bat was caught swiftly by each snake. Snakes captured the bats at the middle of their body. Then, the snakes climbed down the wall and moved toward the rocks (refuge) where the bats were eaten. In both cases, the bats were eaten feet first, and wings last. Ingestion was slow, and the entire process took about 20 min.

We are most grateful to Stephen Corn, M. L. Romero, Zeferino Uribe, Miriam Benabib, and Edna Naranjo-García for their comments on the manuscript.

Submitted by **CORNELIO SÁNCHEZ-HERNÁNDEZ** and **AURELIO RAMÍREZ-BAUTISTA**, Departamento de Zoologia, Instituto de Biología, UNAM. Ap. 70-153, D. F. 14510, México.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in volume 23, number 1.

CAUDATA

AMBYSTOMA MACULATUM (Spotted Salamander). USA: MISSOURI: Pike Co: S edge Ranacker Wildlife Area, 9.5 km N Curryville, Sec. 26 (SE 1/4, SE 1/4), T54N, R4W. 16 November 1991. Brian S. Edmond & Jason D. Blackwell. Verified by D. E. Metter. University of Missouri-Columbia (UMC 1984C). New county record and extends known range 55 km north of closest known locality in Lincoln County.

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

AMBYSTOMA TEXANUM (Smallmouth Salamander). USA: MISSOURI: Putnam Co: near pond next to Dean Cemetery, Rebel's Cove Wildlife Area, 11 km N Livonia, Sec. 32 (SE 1/4, NW 1/4, SW 1/4), T67N, R16W. 29 February 1992. Brian S. Edmond. Verified by D. E. Metter. University of Missouri-Columbia (UMC 1987C). New county record.

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). USA: MISSOURI: Putnam Co: pond on Jean Polson farm, 3 km S Omaha & 8 km NW Livonia, Sec. 23 (SE 1/4, NW 1/4), T66N, R17W. 29 February 1992. Brian S. Edmond. Verified by D. E. Metter. University of Missouri-Columbia (UMC 1986C). New county record.

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

CRYPTOBRANCHUS BISHOPI (Ozark Hellbender). USA: ARKANSAS: Randolph Co: Eleven Point River at a point 1.9 km N Dalton, Sec. 25, T21N, R2W. 8 July 1992. Gary Thatch & Woody King. Verified by V. R. McDaniel. Arkansas State University Museum of Zoology (ASUMZ 18544). New county record; ends speculation by Nickerson and Mays (1973, Milwaukee Public Mus. Publ. Biol. Geol. No. 1:1–106) that Ozark Hellbenders may occur in the lower stretches of the Eleven Point River in Arkansas. Three additional specimens were subsequently tagged and released by authors on 11 July 1992 at Mill Dam (Randolph Co: Sec. 11, T21N, R2W) on the Eleven Point River, 2.4 km inside the Arkansas/Missouri border. The voucher specimen was found in a fisherman's hoopnet at a depth of 4 m, whereas the others were taken while scuba diving in a swift current (2 m in depth). The voucher specimen was collected under Arkansas Game & Fish Commission Scientific Collection Permit No. 34 issued to the senior author.

Submitted by **STANLEY E. TRAUTH, J. D. WILHIDE**, and **PATRICK DANIEL**, Department of Biological Sciences, Arkansas State University, State University, Arkansas 72467–0599, USA.

EURYCEA QUADRIDIGITATA (Dwarf Salamander). USA: NORTH CAROLINA: Randolph Co: 11 km SW Farmer. 27 December 1991. J. C. Beane & S. L. Alford. Verified by A. L. Braswell. NCSM 31683. New county record; extends range ca. 24 km NNE, 43 km NW, and 86 km WSW of nearest records in Stanly, Moore,

and Chatham counties, respectively (NCSM files).

Submitted by **JEFFREY C. BEANE,** North Carolina State Museum of Natural Sciences, Box 27647, Raleigh, North Carolina 27611–7647, USA.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: MISSOURI: Pike Co: pond on Carl Blackwell farm, 8 km NNW Curryville, Sec. 5 (NW1/4, NE1/4, NE1/4), T53N, R4W. 1 February 1992. Brian S. Edmond. Verified by D. E. Metter. University of Missouri-Columbia (UMC 1985C). New county record.

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

ANURA

BUFO COGNATUS (Great Plains Toad). USA: ARIZONA: Apache Co: Lyman Reservoir. 2 July 1988. J. Boundy. San Jose St. Univ. (SJSU A3353); Rt. 666, 11–14 km N St. Johns. 2 July 1988. J. Boundy. SJSU A3354. Verified by D. L. Martin. Extend range south of Little Colorado River in east-central Arizona (Krupa. 1990, *Bufo cognatus*. SSAR Cat. Amer. Amphib. Rept. 457.1).

Submitted by **JEFF BOUNDY**, Museum of Natural Science, Louisiana State University, Baton Rouge, Louisiana 70803, USA.

BUFO MICROSCAPHUS CALIFORNICUS (Arroyo Toad). USA: CALIFORNIA: Riverside Co: Whitewater Canyon: 3–5 km N Interstate 10 on Whitewater Canyon Road, Secs. 27 & 35, T2S, R3E. 10–11 April 1992. Three specimens. Michael A. Patten, Deborah Davidson, & Stephen J. Myers. Verified by Mark Jennings. KU Color Slides 10123–10125. The species has been petitioned for listing under the Endangered Species Act and is protected by the California Department of Fish and Game. This is a new location for the species in California and one of only six past or present localities on the desert slopes. No verified record existed for Riverside County as of late 1960's (Glaser 1970, Nat. Hist. Ser. No. 1, Riverside Mus. Press, Riverside Calif., 40 pp.), but it was "suspected to occur" and is now known from a few localities in the county. Extends range of species about 78 km NE of any known population remaining in the county and 10–15 km NE of the proposed historic range of the species (Sweet 1992, Report USDA Forest Service, Goleta, California, 198 pp.). Past reports from near this location have proved to be erroneous (G. M. Fellers, *in litt.*).

Submitted by **MICHAEL A. PATTEN** and **STEPHEN J. MYERS,** Tierra Madre Consultants, 1159 Iowa Avenue, Suite E, Riverside, California 92507, USA.

BUFO WOODHOUSII (Woodhouse's Toad). USA: TEXAS: Armstrong Co: Palo Duro Canyon, jct. Rt. 207 & Prairie Dog Branch of Red River. 4 July 1992. D. Chiszar. Verified by David Duvall. UCM 56594. First county record (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station, Texas, 434 pp.)

Submitted by **DAVID CHISZAR**, Department of Psychology, and **HOBART M. SMITH**, Department of EPO Biology, both Museum of Natural History, University of Colorado, Boulder, Colorado 80309–0345 and –0334, USA.

HYLA PUNCTATA (Treefrog). ARGENTINA: PROVINCE OF SANTA FÉ, Dept. La Capital: marginal ponds of Arroyo Colastiné (32°04'S, 60°56'W). December 1991. Adriana S. Manzano. Verified by Esteban D. Lavilla. (FML 04828). First record of the species for the province of Santa Fé. The species was previously recorded from Matto Grosso (Brazil), Santa Cruz de la Sierra (Bolivia), and the southernmost record in Argentina was Resistencia (Chaco Province) (27°27'S, 58°59'W). Extends known range south by 4°37' from the previous records along the Parana drainage system.

Submitted by **ADRIANA S. MANZANO**, Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000, San Miguel de Tucumán, Tucumán, Argentina.

TESTUDINES

APALONE SPINIFERA PALLIDA (Pallid Spiny Softshell). USA: TEXAS: Hood Co: 20 km SE Granbury off FM 2174 at Taylor Branch. 14 June 1992. C. T. McAllister. Verified by S. E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 18523). New county record filling a distributional gap between Somervell and Parker counties (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station, Texas, 434 pp.).

Submitted by **CHRIS T. MCALLISTER,** Renal-Metabolic Lab (151-G), Department of Veterans Affairs Medical Center, 4500 South Lancaster Road, Dallas, Texas 75216, USA.

CHRYSEMYS PICTA BELLII (Western Painted Turtle). USA: WYOMING: Johnson Co: Shell Creek, N Buffalo. 27 June 1932. J. Henderson & H. G. Rodeck. Washakie Co: Shell Creek, near Tensleep. 27 June 1932. H. G. Rodeck. Verified by Richard L. Holland. UMC 723, 1053 respectively. Confirm range in both counties as projected without records (Baxter and Stone 1985, Amphibians and Reptiles of Wyoming. Second edition. Wyoming Game and Fish Department, 137 pp.), and extends the documented range about 30–40 km in each county.

Submitted by **DAVID CHISZAR,** Department of Psychology and Museum of Natural History, and **HOBART M. SMITH,** Department of EPO Biology and Museum of Natural History, University of Colorado, Boulder, Colorado 80309, USA.

CLEMMYS MUHLENBERGII (Bog Turtle). USA: NORTH CAROLINA: Gaston Co: 8 km N Gastonia. 2 May 1992. J. F. Green, Sr. Verified by A. L. Braswell. Photographic slides deposited in North Carolina State Museum of Natural Sciences (NCSM AN 92–5–24: DWH 91.49 & DWH 92.06). New county record; verifies county occurrence of A. S. Williams specimen found May 1991. Extends range 38.7 km SW nearest Piedmont province record in Iredell County (NCSM records) and 90.2 km SE nearest Blue Ridge Mountain Province record in Yancey County (Herman 1986, Herpetol. Rev. 17:50). Endangered species permit provided by North Carolina Wildlife Resources Commission.

Submitted by **DENNIS W. HERMAN**, Department of Herpetology, Zoo Atlanta, 800 Cherokee Avenue SE, Atlanta, Georgia 30315, USA, **JAMES F. GREEN, SR.**, Schiele Museum of Natural History, 1500 East Garrison Boulevard, P. O. Box 953, Gastonia, North Carolina 28053, USA, and **BERN W. TRYON**, Department of Herpetology, Knoxville Zoological Garden, P. O. Box 6040, Knoxville, Tennessee 37914, USA.

KINOSTERNON SCORPIOIDES SCORPIOIDES (Scorpion Mud Turtle). VENEZUELA: FALCON: Península de Paraguaná, Municipio Santa Ana, 1 km from Santa Ana (town). 12 November 1987. José Moscó & Tito Barros. Verified by Tito Barros. Museo de Biología de la Universidad del Zulia, Maracaibo (MBLUZ 110). First record for the Península region and northernmost record for the species in South America (Pritchard and Trebbau 1984, The Turtles of Venezuela. SSAR Contrib. Herpetol. 2: 1–414). Speci-

men was found in a temporary pond. Another specimen was observed north of the town of Tacuato, also in the Península, in an artificial permanent pond within a goat enclosure, but was not collected.

Submitted by **ABRAHAM MIJARES-URRUTIA** and **ALEXIS ARENDS R.**, Centro de Investigaciones en Ecología y Zonas Aridas (CIEZA), Universidad Francisco de Miranda, Apartado 7506, Coro 4101–A, Venezuela.

AMPHISBAENIA

ANOPS KINGII (NCN) ARGENTINA: RIO NEGRO: Valcheta. February 1965. Identified by R. Montero. Verified by R. F. Laurent. MACN (Ex CENAI) 136. First documented provincial record. Extends known range ca. 400 km SE Bahía Blanca (Gans and Rhodes 1964, American Mus. Novit. 2186:1–25); CHUBUT: neighborhood of Puerto Madryn. 1967–1970. P. Korchenewsky. Verified by R. F. Laurent. MACN 33890 & 33891. First provincial record. Extends known range ca. 500 km to the south. The high body annuli counts (251, 256) and caudal annuli (21, 22) confirm the idea of their regular increment from northeast to the southwest (Gans and Rhodes 1964, American Mus. Novit. 2186:1–25).

Submitted by **RICARDO MONTERO**, Cátedra Vertebrados, Facultad de Ciencias Naturales, Universidad Nacional de Tucumán, y Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina.

LACERTILIA

CNEMIDOPHORUS GULARIS GULARIS (Texas Spotted Whiptail). USA: TEXAS: Floyd Co: 3.2 km S Briscoe County line, Road 1065. 11 July 1992. R. L. Holland & H. M. Smith. Verified by David Duvall. UCM 56595–6. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas, 434 pp.).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, Boulder, Colorado 80303, USA, and **HOBART M. SMITH,** Department of EPO Biology and Museum of Natural History, University of Colorado, Boulder, Colorado 80309–0334, USA.

EUMECES LATICEPS (Broadhead Skink). USA: PENNSYLVANIA: Lancaster Co: 2.5 km WNW Safe Harbor along Susquehanna River. May 1991. John Kunsman. CM 124295. Verified by John D. Groves. New county record and third record from Pennsylvania (McCoy 1982, Carnegie Mus. Nat. Hist. Spec Publ. 6:1–91); extends range of species 7 km upriver (northwest) from York Furnace, York County (Taylor 1935, Univ. Kansas Sci. Bull. 23:1–643).

Submitted by **C. J. MCCOY,** Carnegie Museum of Natural History, Pittsburgh, Pennsylvania 15213, USA.

EUMECES SEPTENTRIONALIS SEPTENTRIONALIS (Northern Prairie Skink). USA: WISCONSIN: Sawyer Co: Phipps Road at jct. with Gouch Road, ca 100 m W Namekagon River (Sec. 12, T41N, R9W). 16 July 1992. Andrew Cochran, Joseph Cochran, & Philip Cochran. Verified by Gary Casper. MPM P360. A second specimen found along Phipps Road ca 200 m west of the first is currently held alive in the St. Norbert College teaching collection. First county record (Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin, Milwaukee Public Museum, 205 pp.). Occurrence of this species in Sawyer County was predictable on the basis of its association with region H sand deposits (Casper 1992, Abstract, 72nd Annual Meeting, American Society of Ichthyologists and Herpetologists, pp. 80–81.) A "peninsula" of region H sand extends northeast along the Namekagon River from Washburn County into Sawyer County, roughly paralleled by U.S. Rt. 63 (Hole 1976, Soils of Wisconsin, Univ. Wisconsin Press). The Sawyer County skinks were collected not far within the tip of this peninsula. Previously, I have collected specimens near its base, at the confluence of Whalen Creek and the Namekagon River, in Washburn County, ca. 30 km southwest of the Sawyer County capture site. Surveys along U.S. Rt. 63 in Sawyer and Bayfield counties beyond the limit of region H sand failed to produce prairie skinks.

Submitted by **PHILIP A. COCHRAN**, Division of Natural Sciences, St. Norbert College, De Pere, Wisconsin 54115, USA.

HEMIDACTYLUS BROOKII (Limpia-casa). PANAMÁ: PROVINCIA DE PANAMÁ: Distrito de Panamá: Tocumen, 9°05'N 79°22'W, ca. 25 m elevation. 15 November 1980. G. Beleño. Verified by Ronald I. Crombie. Círculo Herpetológico de Panamá (CH 227). New county record. *H. brookii* is found in the old and new worlds, and in the latter was previously known from the West Indies and Colombia (Kluge 1969, Misc. Publ. Mus. Zool. Univ. Michigan 138:1–78). This specimen was collected on the walls of a house in a town close to the Tocumen International Airport. The history of the distribution and abundance of *H. brookii* at this locality is unknown.

Submitted by **ROBERTO IBAÑEZ D., CESAR A. JARAMILLO**, Smithsonian Tropical Research Institute, Apdo. 2072, Balboa, Rep. de Panamá, **FRANK A. SOLIS**, Departmento de Zoología, Universidad de Panamá, Rep. de Panamá, and **FIDEL E. JARAMILLO,** Círculo Herpetológico de Panamá, Apdo. 10762, Estafeta Universitaria, Panamá, Rep. de Panamá.

HEMIDACTYLUS LESCHENAULTI (Bark Gecko). SULTANATE OF OMAN: 4.5 km SW Ra's Suwadi (23°42'N, 57°43'E). 12 October 1989. A. S. Gardner. Verified by E. N. Arnold. BMNH 1988. 220–221. First Arabian record. Appears to be a restricted population in mature *Acacia tortilis* woodland, not closely associated with human activities. However, this site is now rapidly being developed for agriculture, usually involving the felling of the trees, and the future for this species in Arabia is uncertain.

Submitted by **ANDREW S. GARDNER**, Department of Biology, College of Science, Sultan Qaboos University, P. O. Box 32486, Muscat, Sultanate of Oman.

HEMIPHYLLODACTYLUS TYPUS (Indo Pacific Tree Gecko). PITCAIRN ISLAND, PITCAIRN GROUP. Natural History Museum of Basel, Swiss, NMB 8494. Labelled as *Lepidodactylus lugubris*. Exchanged through American Museum of Natural History in 1923. Verified by Aaron M. Bauer. New island record and new island group record (Ineich and Blanc 1989, Atoll Research Bulletin, 1988, 318:1–75).

Submitted by **IVAN INEICH,** Muséum national d'Histoire naturelle, Laboratoire de Zoologie (Reptiles et Amphibians), 25 rue Cuvier, 75005 Paris, FRANCE and Centre de l'Environnement, Antenne Muséum/E.P.H.E., B. P. 1013 Papetoai, Moorea, French Polynesia.

SCELOPORUS UNDULATUS GARMANI (Northern Prairie Lizard). USA: NEBRASKA: Perkins Co: 3.2 km N Chase County line, Road 61. 23–25 June 1992. R. E. Ballinger. Verified by David Duvall. UCM 56590. First county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:44).

Submitted by **ROYCE E. BALLINGER**, School of Life Sciences,

University of Nebraska, Lincoln, Nebraska 68588–0118, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309–0334, USA.

SERPENTES

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). USA: ARIZONA: Apache Co: Rt. 666, 4.5 km N Rt. 60. 13 June 1988. J. Boundy. San Jose St. Univ. (SJSU R6432); Rt. 666, 3.2 km S Nelson Reservoir. 5 August 1988. J. Boundy. SJSU R6436–6437; head of Hobson Canyon, 9.6 km WSW Eagar. 16 October 1988. J. Boundy. SJSU R6446. All verified by Sam S. Sweet. First records for east-central Arizona (Lowe et. al. 1985, The Venomous Reptiles of Arizona. Arizona Game & Fish Dept., Phoenix, 115 pp.).

Submitted by **JEFF BOUNDY**, Museum of Natural Science, Louisiana State University, Baton Rouge, Louisiana 70803, USA.

CROTALUS WILLARDI WILLARDI (Arizona Ridgenose Rattlesnake). USA: ARIZONA: Cochise Co: Whetstone Mountains. 19 September 1991. Luke J. Thirkhill & Brian L. Starrett. Verified by Charles H. Lowe. University of Arizona (UAZ 49176–PSV). Previously known in Arizona from Huachuca, Patagonia, and Santa Rita mountains only. Extends range 10 km N of nearest known locality, Florida Canyon, Santa Rita Mountains. (Fowlie 1965, The Snakes of Arizona. McGraw Hill, New York, 164 pp.).

Submitted by **LUKE J. THIRKHILL** and **BRIAN L. STARRETT**, P. O. Box 9403, Scottsdale, Arizona 85252, USA.

HELICOPS PASTAZAE (NCN) VENEZUELA: ESTADO PORTUGUESA: upper reaches of Río Caparo. 13 February 1983. B. Busto & C. Ramo. Museo de Ciencias Naturales, Guanare (MCNG 737); ESTADO TACHIRA: Río Burgua, 9.2 km S El Piñal. 26 May 1982. D. Taphorn & C. Lilyestrom. MCNG 736. Verified by Joseph T. Collins. These two juvenile males represent new state records and are the second and third known specimens from Venezuela. They agree with previously reported *H. pastazae* in all meristic and mensural features save that MCNG 737 has 89 subcaudals—four fewer than the previous minimum for males (Rossman 1976, Occas. Pap. Mus. Zool. Louisiana State Univ. 50:1–15).

Submitted by **ALLAN L. MARKEZICH,** Department of Natural Sciences, Black Hawk College, Moline, Illinois 61265, USA, and **DOUGLAS A. ROSSMAN**, Museum of Natural Science, Louisiana State University, Baton Rouge, Louisiana 70803, USA.

LAMPROPELTIS TRIANGULUM CELAENOPS (New Mexico Milk Snake). USA: TEXAS: Dallam Co: Rt. 87, 13.75 km NW Dalhart (western city limit). 3 July 1992. H. M. Smith. Verified by David Duvall. UCM 56597. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas, 434 pp.), and first report for the northwestern panhandle of Texas.

Submitted by **DAVID CHISZAR**, Department of Psychology, and **HOBART M. SMITH**, Department of EPO Biology, both Museum of Natural History, University of Colorado, Boulder, Colorado 80309–0345 and –0334.

LICHANURA TRIVIRGATA GRACIA (Desert Rosy Boa). USA: CALIFORNIA: Imperial Co: 33°6'28"N, 114°51'33"W. 17 October 1991. Jerrold J. Feldner. Verified by Robert Bezy. LACM 139667 (PC 1210). Range extension ca. 48 km SE of record for Imperial County, California; helps to fill a hiatus between well-known populations in Riverside County, California, and those in southwestern Arizona (Stebbins 1985, A Field Guide to Western Reptiles and Amphibians. Second ed. Houghton Mifflin Co., Boston, Massachusetts, 336 pp.).

Submitted by **JERROLD J. FELDNER,** Southwestern Herpetologists Society, P. O. Box 7469, Van Nuys, California 91409, USA.

MASTICOPHIS LATERALIS (Striped Racer). USA: CALIFORNIA: Trinity Co: Sec. 30, T5N, R6E, ca. 0.75 km S of end of US Forest Service Road 5N03 on S Fork of Trinity River Trail. 23 May 1992. Photographs verified by Hartwell H. Welsh, Jr. CAS Photographs 44.12 & 44.13. Extends the range ca. 20 km W of previous records in northern California (Bury 1970, J. Herpetol. 4:165–178; Jennings 1983, Cat. American Amphib. Rept. 343.1–343.2). Female, approximately 1000 cm TL. Found 2 m above ground in a canyon live oak (*Quercus chrysolepis*) in mixed evergreen, Douglas-fir (*Pseudotsuga menziesii*) dominated forest on a slope with aspect 130 degrees.

Submitted by **AMY J. LIND**, Pacific Southwest Research Station, Redwood Sciences Laboratory, USDA Forest Service, 1700 Bayview Drive, Arcata, California 95521, USA.

SENTICOLIS TRIASPIS INTERMEDIA (Green Rat Snake). USA: NEW MEXICO: Hidalgo Co: Peloncillo Mountains, Guadalupe Canyon, along a dirt road 0.64 km NE Arizona/New Mexico state line, ca. 56.3 air km S Rodeo, NW 1/4 Sec. 14, T34S, R22W, 1341 m elev. 28 April 1992. Clay M. Garrett. Verified by William G. Degenhardt. Museum of Southwestern Biology, University of New Mexico (MSB 54161). This record represents the first voucher specimen from New Mexico. Occurrence of this species in New Mexico was previously documented by photographs taken by C. M. Bogert and T. A. Snell of specimens from Post Office Canyon in the Peloncillo Mountains, ca. 10 km S Rodeo. These photographs are on file with the Endangered Species Program, New Mexico Department of Game and Fish.

Submitted by **CLAY M. GARRETT,** Department of Herpetology, Dallas Zoo, 621 E. Clarendon, Dallas, Texas 75203, USA, and **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, Endangered Species Program, P. O. Box 25112, Santa Fe, New Mexico 87504, USA.

TANTILLA NIGRICEPS (Plains Blackhead Snake). USA: TEXAS: Dallam Co: Rt. 87, 13.75 km NW Dalhart (western city limit). 3 July 1992. H. M. Smith. Verified by David Duvall. UCM 56593. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas, 434 pp.) and first report for the extreme northwestern panhandle.

Submitted by **DAVID CHISZAR**, Department of Psychology, and **HOBART M. SMITH,** Department of EPO Biology, both Museum of Natural History, University of Colorado, Boulder, Colorado 80309–0345 and –0334, USA.

THAMNOPHIS HAMMONDII (Two-striped Garter Snake). USA: CALIFORNIA: Fresno Co: Arroyo Leona Creek, ca. 0.5 km upstream from the confluence with Arroyo Venado, SW 1/4 NE 1/4 Sec. 10, T18S, R13E. 27 April 1992. Ed Ely. CAS 185349; Fresno Co: Cantua Creek, ca. 2.1 km upstream from confluence with Arroyo Leona Creek, SE 1/4 NE 1/4 Sec. 4, T18S, R13E. 14 June 1992. Ed Ely. CAS 185350. Both verified by Jens Vindum, California Academy of Sciences, and collected under California Scientific Collector's Permit 0630. These records substantiate recent field records by George E. Hansen for nearby Los Gatos Creek (also Fresno County), and extend the known distribution into drainages on the eastern slope of the Diablo Range (Fitch 1940, Univ. California Publ. Zool. 44:1–150).

Submitted by **ED ELY**, Field Associate, Department of Herpetology, California Academy of Sciences, Golden Gate Park, California 94118, USA.

New County Records For Amphibians And Reptiles From Northern Indiana

Minton, List, and Lodato (1983, Proc. Indiana Acad. Sci. 92:489–498) provide a distributional update to Minton's monograph on the herpetofauna of Indiana (1972, Indiana Acad. Sci. Monog. 3). These publications, along with Pentecost and Vogt (1976, Environmental status of the Lake Michigan Region. Vol. 16. Amphibians and Reptiles of the Lake Michigan Drainage Basin. Unpub. Report Argonne National Lab.) greatly enhance our knowledge of the distribution of amphibians and reptiles in Indiana. Despite Indiana's substantial representation in the literature, distributional gaps remain for some well known taxa.

The following specimens represent new county records for five amphibians and eleven reptiles in northern Indiana. All specimens and slides are deposited in the Field Museum of Natural History (FMNH) in Chicago. Identifications were confirmed by Sherman A. Minton and Alan Resetar.

CAUDATA

Plethodon cinereus (Redback Salamander). Starke Co: Oregon Township: Koontz Lake Wetlands. 11 May 1989. A. Resetar. FMNH Slide Collection.

Plethodon cinereus (Redback Salamander). St. Joseph Co: Rum Village, SW sector of South Bend. 29 March 1960. R. E. Gordon and E. Randal. FMNH 247956. Extends the Indiana range into the north central tier of counties.

ANURA

Bufo americanus (American Toad). Starke Co: Hamlet. 17 August 1935. H. Dybas. FMNH 22663. Records exist for *B. americanus* in all surrounding counties.

Rana clamitans melanota (Green Frog). St. Joseph Co: Potato Creek State Park. 11 May 1989. A. Resetar. FMNH Slide Collection.

Rana clamitans melanota (Green Frog). Lake County: Wolf Lake. October 1908. S. F. Hildebrand. FMNH 2842.

TESTUDINES

Chelydra s. serpentina (Common Snapping Turtle). LaPorte Co: New Durham Township: SW 1/4, NE 1/4, Sec. 17, T36N, R4W, Westville Quadrangle. 1 May 1989. A. Resetar. FMNH 242276.

Chelydra s. serpentina (Common Snapping Turtle). Elkhart Co: Little Elkhart River. July 1963. R. E. Gordon. FMNH 246768.

Chrysemys picta marginata (Midland Painted Turtle). LaGrange Co: Little Stone Lake (Mud Lake). 15 June 1943. R. Zangerl. FMNH 206111.

Chrysemys picta marginata (Midland Painted Turtle). Elkhart Co: Washington Township: Pipewort Pond Nature Preserve. 4 June 1989. A. Resetar. FMNH Slide Collection.

Sternotherus odoratus (Common Musk Turtle). St. Joseph Co: University of Notre Dame campus, St. Mary's Lake. R. Mizelle. FMNH 21770–72.

Terrapene c. carolina (Eastern Box Turtle). Elkhart Co: Washington Township: Pipewort Pond Nature Preserve. 4 June 1989. A. Resetar. FMNH 242272 (skeletal remains).

LACERTILIA

Cnemidophorus s. sexlineatus (Six-lined Racerunner). LaPorte Co: Michigan City, NE 1/4, NE 1/4 , NE 1/4, Sec 6, T37N, R4W, Michigan City West Quadrangle. 19 August 1991. A. Resetar, M. Blanford, B. Burke and D. Resetar. FMNH 247400. This is the easternmost record for this species in the Indiana Dunes region.

SERPENTES

Nerodia erythrogaster neglecta (Copperbelly Water Snake). St. Joseph Co: South Bend, South Bend Avenue & Corby Boulevard. 17 June 1965. G. Sechyrist. FMNH 245282. Extends Indiana range westward by three counties from Steuben County into the extreme NE corner of the state.

Storeria dekayi wrightorum (Midland Brown Snake). St. Joseph Co: South Bend. 21 May 1962. R. E. Gordon. FMNH 240472.

Thamnophis sauritus septentrionalis (Northern Ribbon Snake). Starke Co: Oregon Township: Koontz Lake Wetlands. 7 May 1989. A. Resetar. FMNH Slide Collection.

Thamnophis sauritus septentrionalis (Northern Ribbon Snake). LaPorte Co: Cool Springs Township: Pinhook Bog. 7 July 1985. A. Resetar. FMNH Slide Collection.

BOOK REVIEWS

Australian Snakes: A Natural History, by Richard Shine. 1991. Cornell University Press, 124 Roberts Place, Ithaca, N.Y. 14850 (first published by Reed Books Pty. Ltd., 3/470 Sydney Road, Balgowlah, N.S.W. 2093, Australia). 223 pp. Hardcover. $34.95 U.S. ISBN: 0-8014-2737-1.

Has snake ecology come of age? At the 1986 ASIH meeting in Victoria, Canada, in the aftermath of a two-day symposium on snake ecology and behavior, many North American workers on snakes were brought together for the first time and formed a loose organization dubbed the "Snake Ecology Group." Subsequent gatherings brought together many workers on snakes, most notably in 1989 at the First World Congress of Herpetology, and, in the same year, a conference on the biology of pit vipers. In 1990 and 1991, the Snake Ecology Group held informal workshops to discuss on-going research directions, and the group has produced occasional newsletters and a membership directory. These activities, and a number of recent major synthetic publications on snakes (e.g., Pough's *The Diversity of Feeding Mechanisms of Snakes*, Seigel, Collins, and Novak's *Snakes: Ecology and Evolutionary Biology*, Gloyd and Conant's epic monograph *Snakes of the Agkistrodon Complex*, Campbell and Lamar's *Venomous Reptiles of Latin America*, Campbell and Brodie's *Biology of the Pitvipers*), lead me to suggest that research on snakes is flourishing and that snake biology is maturing rapidly. Indeed, the book under review makes a major contribution to that maturation process and may be the best all-around snake book in recent years.

Shine has summarized in one volume much of what is known of the biology of the 172 currently recognized species of Australian

snakes. The book is attractively produced on 8" x 11" (20 x 28 cm) glossy paper in three-column format. It is organized into eight main chapters, and has an appendix (natural history information on Australian snakes), a glossary, bibliography, and index. The main chapters are: Anatomy of a Snake, The Evolution of Snakes, Where Snakes Live, The Behaviour of Snakes, The Sex Lives of Snakes, Snake Life Histories, What Snakes Eat, and Snakes and Humans.

Shine wrote the book, he says, to provide up-to-date information on Australian snakes that is readily understandable to readers throughout the world and to produce the kind of book he wanted to have when he was a teenager: "My goal is to encourage a fresh outlook on these widely feared and misunderstood animals." He succeeds in this approach, presenting a large amount of previously unavailable information (except in the technical literature) in a factual, soundly based, scientific manner. Primary literature is not cited in the text, and the style is free-flowing and relaxed.

A primary feature of the book is its lavish color photographs, of which there are no fewer than 265, portraying 61 species (1 acrochordid, 11 boids, 6 colubrids, 32 elapids, 3 hydrophiids, 2 laticaudids, and 6 typhlopids) of which thirteen of the better-known or more spectacular species (e.g., the diamond/carpet python, *Morelia spilota*; death adder, *Acanthophis antarcticus*; tigersnake, *Notechis scutatus*; and taipan, *Oxyuranus scutellatus*) are each shown in four or more separate photographs. Shine points out that the photographs were contributed by more than fifty colleagues, saying "My main criterion for selection of photographs has been pictures that tell a story rather than portrait shots." And tell a story they do. To classify this diversity of color plates, I grouped them into several categories: close-ups of Australian snakes (77), Australian snakes doing something (53), other scene or event related to Australian snakes (39), Australian snakes in their natural habitats (24), researchers doing something in the field (20), non-Australian snakes (15), Australian lizards and frogs (14), habitat scenes in Australia (12), and anatomical features or products related to snakes (11). On pure economics, at $34.95 (a bargain price for any hardcover book these days) one gets all these spectacular photographs for 13 cents each.

This book is, however, by no means merely a photographic atlas to a regional fauna. Shine's style throughout is to advance interesting ecological patterns and to show them by means of a number of diagrams, maps, and data plots. Many of the patterns probably apply generally to other regions and other ophidian faunas. Several of the maps of continental distributions are fairly sophisticated in being drawn using isopleth lines (e.g., species densities of elapids, pythons, blindsnakes, and colubrids; percentages of elapids and of livebearing elapids). He includes graphs, usually drawn as bicoordinate scatter diagrams or histograms. Data plots include temperature selection in relation to feeding; annual gonadal cycles; average number of young and hatchling body length against female size; growth curves in the water python; seasonal cycles of fat and liver mass; and size-specific dietary diversity.

This is an activist's book: It exudes a strong sense of a modern evolutionary ecologist's synthetic outlook in discovering patterns, and it shows that this information was gained from many years of difficult field research in remote areas throughout Australia. The flavor and excitement of the author's life studying snakes comes through. Incidents such as his narrow escapes from a deadly eastern brownsnake and a saltwater crocodile are chilling. And, his description of boredom in painstakingly gathering information from snakes carrying miniature radiotransmitters ("Most of the snakes I locate are doing exactly the same thing . . . nothing!") is, for those who have done it, brutally sincere. Shine uses this prominent behavior of snakes (doing nothing) to explain the advantages of being a thinbodied ectotherm: ". . . snakes need relatively little food, so can survive difficult conditions by just waiting them out." In contrast to a more familiar furry endotherm, Shine emphasizes many of the features of snake morphology and behavior that seem unusual to humans. He says: "Any attempt to call one of these systems 'advanced' and the other one 'inferior' is bound to be wrong. We need to stop assuming that we are somehow superior to the rest of the living world, and accept that other animals like snakes are not 'lower' than us, but simply different. We should admire them for their abilities, not judge them as 'primitive' or 'inefficient' just because they are different."

There is a mixture of fascinating natural history which leads the reader expectantly onward, and solid biological writing which does not shy away from technical terms. This does beg the question of exactly to whom the book is addressed. Initially, I questioned whether it could be assimilated by an average and interested reader, one who may not necessarily have any training in biology. Although a college or university biology undergraduate probably would be more appreciative of the finer points (and could better cope with the many family names as noted below), I think, overall, the book will appeal to a wide audience. In several places, Shine goes out of his way to take note of the contributions of "amateur" herpetologists and encourages them to take detailed notes on reproduction and growth of their captive snakes, as for some species these data are the only ones we have.

The book is well written and largely error-free, but is not without several small typographical or grammatical mistakes. An excellent cut-away diagram of snake anatomy has tracheal rings identified incorrectly as cartilaginous "ribs." Another otherwise excellent cut-away diagram of the anatomy of the head and venom apparatus labels the quadratomaxillary ligament at the posterior angle of the mouth as a "masseter" muscle. An inconsistency appears in the spelling of the family Anomalepididae (p. 31, phylogenetic diagram of families of snakes) and Anomalepidae (p. 32, text). On page 105, two "the's" are juxtaposed in one line. On page 142, there is a missing line or block of text, as the sentence beginning with "Large frogs . . ." is lengthy and nonsensical and apparently should be two sentences. Whereas most (184) of the legends to the color plates occur outside of the photograph, some (65) are placed within the plate itself. Among these "inside" legends, eight are annoyingly difficult to read because they generally color-match that portion of the photograph which they overlie.

The most often-used technical terms are the common forms of the family names (elapid, boid, colubrid) which may, for the uninitiated reader, pose some difficulty. In the glossary each of the families so identified is defined (e.g., "a venomous snake belonging to the family Elapidae"), but the glossary itself, in containing 56 entries, is dominated by 17 (30%) of these family epithet definitions. Perhaps, because they are so numerous, they should be separated out into a table, and their usage throughout the text explained early on. Several other more substantive, but still minor, criticisms have to do with inconsistencies in the number of genera of elapids, and in the construction and usefulness of the index. Shine provides two useful compendia of the Australian snake fauna: on page 41, a table lists all families, genera, and number of species per genus, and points out that the names of many of the elapids have changed recently, referring the reader to Mark Hutchinson's 1990 paper for an explanation and complete list. Hutchinson's paper, however, does not appear in the bibliography, or anywhere else in the book. The table lists 20 genera of elapids, whereas a few pages later a stylistic diagram of the higher

and species-level taxa shows the number of elapid genera is 25; still later, the appendix of life history information lists 20 genera. Without further background checking, there is no way of determining the correct number of elapid genera, or of referring to a taxonomic authority for this information.

The index is only moderately useful. Its main problem is redundancy in listing the same pages under both the common and scientific names of many species. Examples of dual listings include the taipan (*Oxyuranus scutellatus*), 22 references; the water python (*Liasis fuscus*), 26 references; the king brown (*Pseudechis australis*), 15 references; the diamond python (*Morelia spilota*), 26 references; and the tigersnake (*Notechis scutatus*), 41 references. A number of additional species have the same redundancy problem (but fewer references), whereas for others the page references do not match. Also, the index provides no indication of the type of material referred to, whether topical, tabular, or illustrative. Thus, the utility of the index is minimal.

As mentioned above, there are so many high quality photographs throughout the book, providing a taxonomic index to them would have been most useful, especially as each is fully labeled by both common and scientific name. On one page in the book, to give a specific example, five pictures of the western brownsnake, *Pseudonaja nuchalis*, show the dramatic geographic variation in coloration and pattern in this remarkable snake. Shine points out that whereas this snake traditionally has been treated as a single species, in reality it probably comprises several species, yet the access to the page of photographs showing the snake is not apparent in the index.

A culmination to Shine's approach may be found in the appendix which provides a comprehensive table summarizing the natural history information of the best known snakes in Australia. The appendix provides five full pages of extremely valuable information: average body size (snout-to-vent length) of hatchlings, adult males, and adult females; reproductive mode; average number of offspring; and food habits (percentage of dietary composition of seven major prey groups). The appendix is well organized, listing dozens of species by family, common, and scientific name in alphabetical sequence of generic names. Following the appendix and the glossary, a useful seven-page bibliography lists relevant books and scientific papers, the latter grouped by higher taxon. No fewer than 68 citations are to papers authored or co-authored by Shine, demonstrating his productive scientific output on Australian snakes.

Those who enjoy good natural history writing with a firm foundation of good science will like this book. Rick Shine is to be congratulated for making available in an attractive, affordable package, a scientifically sound herpetological book on a fascinating group of animals. Here, he synthesizes more than twenty years of his own research efforts. Despite my noting a few errors, these certainly are minor and do not detract from the value of the book. It is a bargain for the price. More importantly, it deserves wide recognition as a natural history book with a solid underpinning of modern evolutionary thinking. Shine's book provides a fascinating read for the general biologist or vertebrate zoologist, the snake culturist and captive breeder, and especially for the herpetologist interested in, or even doing research on, snakes.

Atlas de Repartition des Batraciens et Reptiles de Corse, by Michel Delaguerre and Marc Cheylan (and collaborators). 1992. Parc Naturel Regional de Corse, B.P. 417, F-20184 Ajaccio, France. 128 pp. Softcover 120 FF (approx. $25.00 U.S.).

Lisez-vous francais? Although one will need to brush up one's French to make full use of this book, all herpetologists are likely to appreciate the attractive layout and numerous color photographs of the volume. Despite the title of the work, this is far more than a collection of distribution maps; it is an introduction to the herpetofauna of one of the most biologically interesting and scenically spectacular areas of Europe. Corsica, France's largest Mediterranean island, covers an area of 8722 km^2 and reaches elevations of up to 2700 m. The herpetofauna (including marine species) comprises seven species of amphibians and 13 reptiles. Of these, two amphibian species, *Euproctus montanus* and *Discoglossus montalentii*, and two reptile subspecies, *Archaeolacerta b. bedriagae* and *Natrix natrix corsa* (the latter questionably valid), are Corsican endemics. A further nine species are regional endemics, also occurring on neighboring Sardinia.

This book is based primarily on recent records of specimens from the island, over 2700 in all, most since 1979. The bulk of the volume is formed by individual species accounts, each 2-4 pages in length. These present an overview of the distribution, natural history, and past research on the animals, with special reference to information relating to Corsican populations. Conservation status, human threats, and local names are provided in at least some instances. The distribution of each species within Corsica is shown on large point-locality maps of the island, each of which also presents an elevational profile of the species, indicating the absolute and relative percentages of observations of each taxon within each 100 m elevational band. The resolution of the maps is far greater than that available in the more general atlas of France as a whole (Castanet and Guyetant 1989) and provides the basis for meaningful distributional analyses.

In addition to the taxonomic accounts, a short historical overview of the Tyrrhenian herpetofauna, a geologic, climatic, and vegetational introduction to Corsica, and a detailed biogeographic section are provided. The last of these presents a wealth of information. The distribution of amphibians and reptiles on 111 smaller islands, islets, and rocks surrounding Corsica is presented in tabular form, and intra-Corsican analyses of species richness and environmental correlates of distribution are presented. The distributional patterns of all terrestrial vertebrates are also discussed in a broader Mediterranean context and maps, tables, histograms, and graphs are effectively used to highlight particular points. Common island phenomena, such as gigantism/dwarfism and melanism are also reviewed, and two "island specialists," *Phyllodactylus europaeus* and *Podarcis tiliguerta*, studied in detail by Delaguerre and Lanza, respectively, provide the focus for a discussion of insular geographic variation. Unfortunately, however, there are few explicit connections made between phylogenetic and biogeographic patterns.

The layout of the volume as a whole is attractive, and there are over 70 illustrations, exclusive of maps and graphs. Photo quality throughout ranges from fair to excellent and although the color reproduction is very good, a number of animal shots suffer from poor composition or excessive shadowing. The photos are augmented by a number of line and half-tone drawings, illustrating such subjects as larval amphibians and sequential views of behavioral events.

Typographic errors, such as the frequent misspelling of the

names of German authors, are reasonably unobtrusive and an errata sheet provided with the book corrects most of the more significant problems, such as incorrect maps for the species of *Discoglossus*. The narrative form of the species accounts makes the quick referencing of basic biological information somewhat difficult and the absence of an index of any kind is a real drawback. The rather specialized Corsican focus of the volume may put off some North American herpetologists with only a casual interest in the European herpetofauna and the many available European field guides are likely to meet the requirements of these readers more adequately. However, for those with special interests in the amphibians and reptiles of the Mediterranean, or in island biogeography in general, this inexpensive book will be a valuable and attractive addition to the library.

Florida's Fabulous Reptiles and Amphibians, by Pete Carmichael and Winston Williams. 1991. World Publications, P.O. Box 24339, Tampa, Florida 33623, USA. 120 pp. Softcover. $15.95 U.S.

From alligators to sea turtles, you will find 120 pages packed with fabulous photographs and factual natural history notes on Florida's herpetofauna. The cover of this coffee-table style book indicates that it deals with snakes, lizards, alligators, frogs, and turtles. In addition to those taxa it includes an amphisbaenid, a nice comparison of alligators and crocodiles, and a section on salamanders. The book, however, does not describe every species known to occur in Florida. Some of the panhandle species are missing. Every animal considered, however, is beautifully illustrated, including many introduced species. For example, the authors include excellent photos of curly-tailed lizards (*Leiocephalus carinatus*), and knight anoles (*Anolis equestris*) from Miami, and a brief discussion of the northward progress of the brown anole (*Anolis sagrei*) through the state.

Most pages have one or two highlighted paragraphs which the authors use to place an individual taxon into a broader ecological, behavioral, or evolutionary perspective. A section on rattlesnakes includes paragraphs on rattlers and bulldozers, fabulous fangs, the remarkable strike, rattlesnake roundups, and deadly encounters. Conservation is emphasized throughout. In particular, the potential negative effects of introduced species are dealt with in several places in a manner that promotes the value of maintaining the native faunal integrity. The authors acknowledge a lengthy list of consultants (especially Peter Meylan) for their contributions. These consultants did a fine job of assuring the accuracy of the text. Folks who read this book will come away with a good feeling about amphibians and reptiles and a sound introduction to the several hundred species that call Florida home. The stated range of each taxon is limited to its distribution within Florida. Future editions would benefit from inclusion of the entire geographic range of each species.

Considering the quality, scope, educational value, and price, this book should be in the library of every North American herpetologist. It is especially appropriate to use as a gift to a young budding herpetologist, who just might grow up to study some of Florida's Fabulous Reptiles and Amphibians.

PUBLICATIONS RECEIVED

An Indexed Bibliography of the Herpetofauna of Florida, by Kevin M. Enge, and C. Kenneth Dodd. 1992. Florida Game and Fresh Water Fish Commission, Nongame Wildlife Program Technical Report No. 11. 231 pp. Softcover. $2.70 donation suggested. (Available from Nongame Wildlife Section, Florida Game and Fresh Water Fish Commission, 620 S. Meridian Street, Tallahassee, Florida 32399, USA).

A bibliography of 2820 entries on the Florida herpetofauna including references through January 1992. The bibliography is thoroughly indexed by scientific name, common name, and topic. The 25 topics used in the index are clearly defined and consistently applied.

Catálogo Taxonómico, Biogeográfico y Bibliográfico de las Ranas de Venezuela, by Enrique La Marca. 1992. Cuadernos Geográficos No. 9. 197 pp. Softcover $9.00 U.S. (postage included). (Available from Facultad de Ciencias Forestales, Universidad de Los Andes, Via los Chorros de Milla, Mérida, Venezuela).

A review, in Spanish, of the 202 species of Venezuelan frogs. Systematic accounts include primary references to types and the original name citations as well as statements of type localities, general distribution, synonyms, and taxonomic comments. The distributional section consists of 76 shaded range maps showing distributions within Venezuela. Also included are a bibliography of 500+ references to Venezuelan frogs, a list of institutional acronyms mentioned in the text, a taxonomic list of all species, and an index of scientific names.

Erratum

In the Life History Note concerning *Liolaemus lutzae* (Rocha 1992. Herpetol. Rev. 23(2):60), an incorrect sample size was given for the number of lizards examined. The correct sample size of the lizards analyzed was 158 adults.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).***HR*** especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Life History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints (8 x 10 inch preferred).

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc., 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Life History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles, Techniques Articles, Points of View, as well as news notes and other material, should be sent to the Editor.

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of three reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Life History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

SOCIETY FOR THE STUDY OF AMPHIBANS AND REPTILES

NEW PRICE for the

Catalogue Of American Amphibians And Reptiles

The catalogue consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere.

COMPLETE SET: NUMBERS 1 - 530	$200.00
INDEX TO ACCOUNTS 1 - 400: Cross-referenced, 64 pages	$5.00
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$5.00
IMPRINTED POST BINDER: (note - two binders are needed for the 505 accounts)	$25.00
INCOMPLETE SET: NUMBERS 1 - 190	$60.00
191 - 410	$70.00
411 - 530	$75.00

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the ***Journal of Herpetology*** (4 issues annually), ***Herpetological Review*** (4 issues annually), and occasional issues of ***Facsimile Reprints in Herpetology***. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1992

Student member	$25.00*	Sustaining member	$60.00*
Regular member	$35.00*	Contributing member	$85.00*

Institutional subscription.....$60.00

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles***: subscription is $15.00 annually ($3.00 air delivery surcharge if airmail is desired.). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

SSAR BUSINESS

SSAR Grants-In-Herpetology

Proposals are now being accepted for the 1993 SSAR Grants-in Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address educational projects, speakers' fees, regional research, defrayment of one-time-only costs, or other purposes that would strengthen regional societies. Proposals may be submitted by regional herpetological societies or by individual members and must be accompanied by a letter of support from the current president of the regional society.

2. HERPETOLOGICAL RESEARCH OR EDUCATION IN ZOOS. Proposals may address any herpetological endeavor conducted in zoos, such as improvement of displays, interpretive graphics, husbandry or behavioral research. A letter of support from the herpetological curator or the director of the sponsoring zoo must accompany the proposal.

3. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species. Proposals must be from individuals only and must be accompanied by a letter of support from another member of the SSAR.

4. FIELD WORK. Proposals may address support for travel to ecological study sites or for survey collections. Proposals normally submitted in the CONSERVATION or GRADUATE STUDENT RESEARCH categories should be submitted here if travel or field station support is sought. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

5. GRADUATE STUDENT RESEARCH IN HERPETOLOGY. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only. Applications must be accompanied by a letter of support from the student's major advisor or committee chairperson.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR with the exception of those applying in the REGIONAL HERPETOLOGICAL SOCIETY category. Applicants are limited to submission of one proposal in one category per year. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following: (A) BACKGROUND AND OBJECTIVES of the proposed project. (B) METHODS of carrying out the project. (C) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). (D) BRIEF RESUME of the applicant or project coordinator. (E) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages excluding resume and budget.

Applicants must designate to which of the five categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than 31 DECEMBER 1992 to be considered. Failure to meet the guidelines may result in elimination of a proposal from consideration. The awards will be announced by 1 April 1993. Successful applicants will be expected to submit a written report of the results of this support within a reasonable amount of time after the project year is completed. They are also encouraged to submit the results of research projects for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to:

Dale Belcher, Chair (505) 843-7413
SSAR Grants-in-Herpetology
Rio Grande Zoo
903 Tenth St. SW
Albuquerque, New Mexico 87102-4098, USA.

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number and/or size of awards. Your tax-deductible contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

Thanks to SSAR Contributors

SSAR wishes to acknowledge the support of the following Contributing and Sustaining Members. Their financial support of Society activities is greatly appreciated.

Contributing: M. L. Anderson, R. G. Arndt, J. R. Bailey, A. E. Greer, L. R. Miller, M. Miller, N. J. Millichamp, P. E. Moler, R. Reifsnyhder, R. Ruibal.

Sustaining: R. D. Bartlett, H. B. Bechtel, J. D. Congdon, M. A. Dloogatch, W. A. Dunson, C. R. Edmondson, H. M. Fischer, H. W. Greene, P. A. Jaffray, R. Jooris, W. H. Lowery, J. Mayne, T. J. Monahan, G. L. Nystuen, P. D. Oldak, M. M. Patton, the late R. M. Zantzinger.

NEWSNOTES

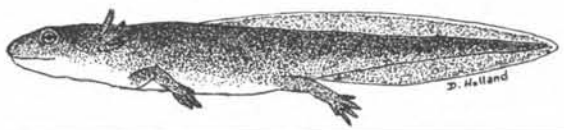
Charles Stearns Grants-In-Aid For Herpetological Research At California Academy Of Sciences

The Department of Herpetology is pleased to provide limited financial aid to graduate students who wish to visit our collections to support their research in systematics.

Proposals should include a short—no more than one page—description of the research project, as well as a letter of support from the student's faculty advisor.

Proposals will be due on 15 October 1992, with notification by 1 December 1992. Grantees will be expected to complete their Academy visit by 15 September 1993.

Send proposals to:



Herpetology Research Grants
Department of Herpetology
California Academy of Sciences
Golden Gate Park
San Francisco, California 94118-4599, USA
Tel. (415) 750-7037.

Chicago Academy of Sciences Collection Records Computerized

The Chicago Academy of Sciences is pleased to announce the computerization of its herpetological specimen records, comprising nearly 20,000 specimens. Most of the collections date from the 1920s through the 1940s, although some specimens were collected as early as the 1850s. The geographic areas best documented are Arizona, Illinois, Indiana, Missouri, Georgia, Tennessee, and Wisconsin. Ninety-eight percent of the Academy's herpetological holdings are from the continental U.S.

Information requests are welcomed from all serious researchers. For more information contact:

Ron Vasile
Collections Manager
Chicago Academy of Sciences
2001 N. Clark Street
Chicago, Illinois 60614, USA.

REGIONAL SOCIETY NEWS

New Regional Societies

Please add the following regional societies to your directories:

Rhode Island Herpetological Association
P.O. Box 29474
Providence, Rhode Island, USA

South/Central Texas Herpetological Society
c/o Niels Saustrup
1405 Rabb Road
Austin, Texas 78704, USA

Southern New England Herpetological Association
470 Durham Road
Madison, Connecticut 06443, USA

Wahsatch Alliance of Herpetoculturists
c/o T.A.H.
P.O. Box 1907
Casper, Wyoming 82602, USA

The San Antonio Herpetological Society is no longer extant.

Regional society officers are encouraged to submit address changes to the SSAR Regional Society Section Editor (see inside front cover of HR) and new societies are invited to announce their existence in this column. Established groups are also invited to submit short descriptive articles about their societies for publication in this column.

LEGISLATION & CONSERVATION ALERT

This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered herps. We are in need of more information, especially at the state/province and regional levels. Please send pertinent information to the Section Editor.

The following final and/or proposed listings, regulations, and general information have been announced by governmental regulatory agencies. Pertinent Federal Register (FR) citations are given for U.S. notices.

USA, Massachusetts: The Massachusetts Natural Heritage and Endangered Species Program added two snakes to their list of Endangered, Threatened, and Special Concern species on 31 January 1992: *Elaphe obsoleta* (State Endangered) and *Carphophis amoenus* (State Threatened). A copy of the complete Endangered Species Act Regulations, 321 CMR 10.00, may be obtained from the State House Bookstore, State House, Rm. 116, Boston, Massachusetts 02133, USA. The cost is $2.25 plus $1.50 for postage and handling.

USA, Virginia: The Virginia Department of Game and Inland Fisheries (VDGIF) is proposing a 1993 Legislative Bill to amend S29.1-417 of the Code of Virginia by adding a subsection to require a permit for the taking of amphibians, reptiles, and aquatic invertebrates for commercial use. Comments and suggestions from the herpetological community to help make this an effective conservation strategy would be appreciated by the VDGIF, 4010 Broad Street, Box 1104, Richmond, Virginia 23230, USA.

USA: Federal Register, Vol. 57, No. 93, 31 May 1992. The listing status of the following species has changed. From Category I to II: *Alligator sinensis, Crocodylus niloticus* (Ethiopia, Kenya, Madagascar, South Africa, Uganda, and Tanzania populations), *Crocodylus porosus* (Indonesian population). From Category II to I: *Crocodylus cataphractus* (Congo population), *Crocodylus niloticus* (Cameroon, Congo, and Sudan populations), *Osteolaemus tetraspis* (Congo population), *Clemmys muhlenbergii* (United States). Added to Category II: *Clemmys insculpta* (United States), *Corucia zebrata, Phrynosoma coronatum*, and *Vipera wagneri*.

USA: The Nature Conservancy: A memorandum was issued by the Eastern Regional Heritage Task Force urging all TNC and Natural Heritage Program Staff to report any observed illegal taking of bog turtles (*Clemmys muhlenbergii*) to USFWS law enforcement officials. The bog turtle was added in March to Appendix I of CITES, thus prohibiting international trade in the species.

KURT BUHLMANN
SSAR Conservation Committee

ARTICLES

Vertical-Tree Ambush Posture In *Crotalus horridus*

An adult male timber rattlesnake (*Crotalus horridus*, total length 122 cm, body mass 954 g) captured on 27 April 1991 was radiotracked and observed in northeastern New York. Habitats and climate of the study locality are described by Brown (1992). The snake was one of six animals tracked between 19 May and 11 October 1991. Transmitters were inserted intraperitoneally (cf. Reinert 1992; Reinert and Cundall 1982).

The rattlesnake was observed on nine dates as it moved distances of about 75 to 300 m between successive locations prior to its return migration to its hibernaculum. On four occasions this snake was observed in a previously undescribed ambush posture

FIG. 1. Vertical-tree ambush posture in adult male *Crotalus horridus* in northeastern New York, 25 August 1991. (Photo by G. Lemmo)

at the base of a tree (Fig. 1). When first seen in the posture on 26 May, the snake was stretched at the base of a large (65 cm DBH) red oak tree (*Quercus rubra*) with its head facing upward and its neck looped against the tree trunk. The height of its head was ca. 25-30 cm above ground level. On 22 August, the snake was against a small (32 cm DBH) eastern hemlock tree (*Tsuga canadensis*). The body of the snake extended around the side of the trunk, and its head was directed vertically about 30-35 cm above ground level. On 25 August, the snake was similarly observed at the base of a small (25 cm DBH) shagbark hickory tree (*Carya ovata*).

On 29 August the snake was again observed at the base of a small (25 cm DBH) red oak tree. To test the ability of the snake to strike prey while in this posture, a freshly-killed adult eastern chipmunk (*Tamias striatus*) was grasped in tongs and slowly lowered against the tree trunk toward the snake from a height of 1 m. The snake tongue-flicked when the chipmunk was about 10 cm above it, and, as the chipmunk was moved closer, the snake struck it quickly from this head-up position without moving any other part of his body. The bitten chipmunk was moved (in jerky fashion to simulate stress) down the bark of the tree next to the snake and dragged across the leaf litter to a point about 1.5 m away. After about 20 min the snake had advanced slowly out from his original position. The snake's head was raised about 20 cm above the ground, motionless, facing the chipmunk. After ca. 45 min the snake had moved no farther than about 25 cm from the base of the tree. The chipmunk was then moved closer to the snake's head and observed as the snake investigated and began to swallow it head first. Thirty minutes later the snake had completed the meal and was crawling slowly away from the ambush tree.

These observations augment those of Reinert et al. (1984) on the foraging behavior of *C. horridus* in Pennsylvania where timber rattlesnakes use fallen logs as ambushing sites. This vertical-tree ambush posture, however, has not been described previously for *C. horridus* or for other viperids (Greene and Santana 1983) as a method for ambushing arboreal prey. Whether the posture is a characteristic of some proportion of the snakes in the local population, or is a learned behavior by a few individuals, is a question whose answer will expand our understanding of the role of diverse foraging strategies in snakes.

Acknowledgments.— A grant to Skidmore College by the W. M. Keck Foundation supported this faculty-student collaborative research. We appreciate Howard K. Reinert's assistance in initial surgical implantation of transmitters and, along with Michael V. Plummer, in giving much useful advice. We thank Hank Ayers, Willie Bencze, Maureen Jones, Barbara Kermeen, Gerard Lemmo, Pamela Reppert, and the late Ruth M. Zantzinger for assistance. Charles W. Boylen provided lab space at the Fresh Water Institute, a field station of Rensselaer Polytechnic Institute. Brown's studies of *C. horridus* are conducted under a New York State scientific collecting permit.

An Important New Book

HERPETOLOGY

CONTEMPORARY RESEARCH ON THE BIOLOGY OF AMPHIBIANS AND REPTILES

HERPETOLOGY is at once an old and yet also a newly revitalized field of research. It was founded in the 18th and 19th centuries on taxonomic, anatomical, and distributional studies, but during the last century, trends in biology and science fragmented the study of amphibians and reptiles into narrower and more disconnected disciplines. The recent renaissance of holistic approaches has helped to transcend these disciplinary boundaries, enabling herpetologists to become active participants and even leaders in this rebirth of the integrated study of animals, as the authors in this new volume demonstrate.

The "New Herpetology" was formalized in 1989 at the First World Congress of Herpetology, held in the United Kingdom, which brought together more than 1000 specialists on amphibians and reptiles from some 60 countries. Ecologists, anatomists, conservationists, geneticists, physiologists, paleontologists, and others who span the spectrum of biology met to share ideas and information. There was a general acknowledgment of the value of broadly integrated approaches to the study of a group of organisms, and the recognition that modern herpetology represents a vigorous and cohesive discipline of enduring significance.

The main feature of the Congress was a series of plenary lectures chosen to emphasize the range of current herpetological studies and to highlight those topics in which research on amphibians and reptiles have made major contributions to biology. This book contains the revised and updated versions of those lectures by authors who are among the world's leaders in their respective fields. Together, these essays demonstrate the breadth of modern herpetology and its continuing vitality as a discipline.

The volume also contains a detailed, illustrated summary of the meeting, with a list of all participants in symposia, workshops, roundtables, poster sessions, and other events. Included is a complete list of delegates and their addresses. This volume represents the summary of record for the First World Congress of Herpetology and a synopsis of current research in our discipline. It is an excellent introduction to modern herpetology for students and others interested in the biology of amphibians and reptiles.

Specifications: 225 pages, format 8 ½ by 11 inches (22 by 28 cm), 20 photographs, numerous tables and graphs, clothbound in library-grade buckram. To be published December 1992.

LIST OF CONGRESS DELEGATES WITH ADDRESSES

Prices and Ordering

The pre-publication price (before 15 November 1992) to SSAR members and to Delegates of the First Congress is $20. The price to all other persons and to institutions is $28. (Packing and shipping per volume: USA add $2, other countries add $4).

Numbers of copies ___ at $___ per copy, plus $___ total packing and shipping: total amount enclosed: $___.

Send orders to: Dr. Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, St. Louis University, St. Louis, Missouri 63103, USA. (Telephone 314-658-3916; fax 314-658-3117). Overseas customers must pay in USA funds using a draft drawn on American banks (include an additional amount to cover bank conversion charges) or by International Money Order. MasterCard or VISA are accepted (provide account number and expiration date); a 5% bank charge will be added to your account. A complete list of SSAR publications and applications for Society membership are available on request from Dr. Aldridge.

Omphalopagus Twins In *Chelonia mydas*

Monozygotic twinning is generally considered to be a form of aberrant development, although some evolutionary benefits have been postulated for armadillos, as monozygotic twins occur regularly in *Dasypus* (Benirschke 1981). For the most part, however, monozygous twinning is associated with structural and physiologic abnormalities which produce hazard to one or both embryos. In humans, such development can be associated with twin-twin transfusions, cord and body entanglements and, probably most significant, fusions or so-called Siamese twins. The latter phenomenon is termed "Pagus" (Greek for fixed) and the prefix for the given pagus fetus designates the body parts involved. For example, omphalopagus refers to fusion at the umbilicus with varying degrees of fusion with derivatives of the umbilicus including vitellin vasculature and intestines. The stimulus for such events occurring in nature is generally unknown.

Monozygotic twinning is known to occur in turtles. The frequency of this event may be region and species specific. For example, in a study of twin leatherback sea turtles, *Dermochelys coriacea*, a frequency of 0.0383 - 0.2000 pairs per female per year, or 2.6% of nests (N=468 nests) was recorded. Full term twin embryos were never observed (Eckert 1990). Another report cited twins in 4.1% of examined nests (Whitmore and Dutton 1985). In a large series from Tortuguero, Costa Rica, Fowler (1979) examined hatchling success and nest predation in *Chelonia mydas*. Of 11,813 eggs studied, 1977 were unhatched and in this subset, three sets of twins were identified. Additionally, one two-headed embryo near hatching size was noted (Fowler 1979). A single case report of a fused twin green sea turtle documented apparent omphalopagus twinning. This very brief report was without photographs or descriptive pathological or anatomical assessment (Hewavisenthi 1989). An instance of thoraco-omphalopagus twin turtles has been documented in *Pseudemys scripta*. The twins lived to about four months of age and had only one set of shared viscera (Szabuniewicz and McGrady 1967).

We report here an instance of omphalopagus twins in the green turtle, *Chelonia mydas*, and describe in detail the histopathologic and anatomic relations of this fusion. The twins were found in an excavated nest located south of the Sebastian Inlet in Indian River Co., Florida (28° 50" W, 80° 30" N). The nest was laid on 23 August 1990, emerged on 13 October 1990, and was inventoried on 14 October 1990. In this study, 35 of 54 nests were examined during the 1990 hatching season. Out of 4425 eggs, only one set of twins (this case) was identified. There were four unsuccessful emergents from this clutch of 125 eggs. Of these, three were mid-term and one egg contained fused twins. Additionally, there were 17 blighted eggs showing no sign of embryonic development. The twins were preserved in 10% buffered formalin for further study. The fused mid-term turtles were of unequal size and attached by a thin membrane near the umbilicus. They were oriented in opposite directions (Fig. 1). Both were well formed, except that the smaller turtle had its left forelimb extended, rather than pointing backwards, as would be normal. The twins were so closely attached that they were unable to move freely within the egg.

The larger of the two embryos weighed 15.5 g with an exteriorized yolk (3.2 g, 1.5 cm diam) extending through a round opening in the plastron into the abdominal cavity and connected with the intestines. Approximately one fifth of the yolk was internal. Dissection of the embryo revealed only a somewhat compressed left thoracic cavity and relatively small intestines (compared with the smaller twin). The smaller of the two embryos weighed 6.2 g and, with the exception of the extended foreleg, it appeared normal. Its connection to the larger twin was through a membranous vascular stalk that issued from a 0.3 x 0.3 cm round opening in the plastron and which connected to the intestines. No yolk was present and its intestines were longer and better developed than those of its twin.

Histologic examination confirmed muellerian ducts and primitive ovaries in both embryos. In the larger twin, the intervening epithelium-lined structure contained (l) vitelline vessels, (2) yolk, and (3) no intestine. In the smaller twin, the structure contained (l) vitelline vessels, (2) no yolk, and (3) a protruding portion of intestines.

The described findings are consistent with monozygotic female omphalopagus twin green turtles. The runted twin may have become retarded due to spatial constraints or vascular phenomena, such as transfusion syndrome. In such a condition, nutrient supplies may be shunted by vascular channels from a runted to a plethoric twin. This is a phenomenon observed in mammals but the physiologic response to such putative events in turtles is unknown. It is of interest that the fused turtles described by Hewavisenthi (1989) were discordant in their sizes (one measured 4. 2 cm and the other, 2.5 cm). Based on the extent of the connection and the presence of yolk, monozygotic division of the embryo probably occurred after gastrulation during formation of the yolk stalk.

Observations On The Defensive And Aggressive Behavior Of The Leatherback Turtle (*Dermochelys coriacea*) At Sea

We report an unusual encounter with an adult leatherback turtle (*Dermochelys coriacea*) off the coastal waters of the Republic of Palau in the western Pacific Ocean on 17 May 1991. We were plying the waters about 1 km south of Ncheangel (Kayangel) Atoll in the channel between the Atoll and Kossol Reef, approximately 8° 1' 30" N; 134° 44' E. The weather was sunny, the northerly wind light, and the ocean calm. Our boat was an open 7 m fiberglass runabout equipped with two 75-hp outboard engines.

At midday we noticed a large animal surfacing several times as we fished about 300 m away. After 5-10 min we motored toward the unidentified creature and found it to be a leatherback turtle interacting with a large (2 m) gray reef shark (*Carcharinus* sp.). The two animals were behaving aggressively, swimming rapidly about one another, with the turtle frequently breaking the surface alongside our boat. We stopped the boat and watched. The turtle swam erratically, repeatedly surfacing and exposing head, carapace, and flippers, often creating a frothy wake of bubbles as it resubmerged. At one point the turtle swam rapidly toward the shark, forcing it to take evasive action by darting away. Although we at first thought that the turtle had possibly been bitten and wounded by the shark, in fact the turtle appeared uninjured with all flippers intact and no blood in the water. After about 5 min the shark swam away and we did not see it again. The turtle, however, maintained an interest in our boat and continued to swim underneath and beside us, acting much as it did in the presence of the shark.

The turtle then began short rushes toward us, solidly ramming the underside of our boat. The turtle typically made shallow dives (5-15 m) in between each surfacing and hitting of the boat. It appeared to be ramming us with the leading edge of its carapace, or the upper part of the carapace itself, as opposed to its head. Although this butting was solid and could have thrown an inattentive person off one's feet, we did not notice any blood in the water or damage to the turtle's carapace. The turtle continued to surface frequently, lifting its head, a fore-flipper, and part of its body out of the water. On at least one occasion it surfaced upside down and swam several meters with its plastron up (Fig. 1). After 5-10 min of this behavior, and after hitting our boat half a dozen times, the turtle appeared to lose interest and began to swim away.

At this point, two members of our crew (C. Cook and N. Idechong) donned masks and snorkels and entered the water, jumping in on opposite sides of the boat. When Cook was 3-4 m from the boat the turtle came immediately and aggressively toward him. The turtle approached with mouth agape, but veered away within the last few meters when Cook made a threatening gesture by spreading his arms. Cook climbed quickly back into the boat, whereupon the turtle shifted attention to Idechong, who had lost sight of Cook and was searching for him at the stern of the boat. As the turtle approached, Idechong swam between the propellers of the two outboard engines. The turtle came from below, mouth open, evidently intent on biting the swimmer. Idechong delivered several kicks to the turtle's head, and the turtle backed off. The turtle did not or was not able to bite the swimmer's foot, and at the first opportunity Idechong climbed back into the boat.

The turtle hit the boat several more times, and then appeared to lose interest, moving farther and farther from us. When the turtle was no longer in sight, we started our engines and motored away. The entire encounter lasted 15-20 min.

The turtle was an adult whose carapace length we estimated to be ca. 1.5 m or more. Leatherbacks with a carapace of this length would be expected to weigh about 450 kg (Anonymous 1975, Van Denburgh 1924). The tail was short and the turtle was probably a female. We took several photographs of the animal as it surfaced around our boat (photos on file at the U.S. Fish and Wildlife Service Honolulu Office). The leatherback is occasionally reported in Micronesia (Pritchard 1977) and is thought to be an uncommon or rare species in Palau and Micronesia. Noah Idechong, who grew up in Palau and spent much time on the water, had seen only one leatherback prior to this encounter.

FIG. 1. Adult leatherback turtle surfacing upside down.

Based on our discussion with others familiar with sea turtles, the behavior of this leatherback was unusual (G. Balazs, T. Fritts, J. Woody, J. Richardson, pers. comm.). However, there are several published accounts of leatherbacks that have acted aggressively in response to humans or sharks (Cropp 1979, Schroeder 1965, Van Denburgh 1922). In one of two encounters described by Schroeder (1965), a large leatherback was observed somersaulting over backwards, making repeated vertical dives, and ultimately attacking Schroeder's boat—behaviors similar to those we observed. Cropp

(1979) detailed an encounter of a leatherback and shark off the coast of Australia. According to Cropp, a great white shark circled under a leatherback which was swimming on its back, wildly thrashing all four flippers, flipping, rolling, and diving on an erratic course. When Cropp maneuvered his boat between the turtle and shark, the turtle continued its tumbling and thrashing on the surface, evidently regarding the boat as another predator. We speculate that the aggressive display of the leatherback toward our boat was the result of its encounter with the shark. The turtle, which was clearly sparring with the shark, evidently considered us to be a threat as well.

Reports of turtles being bitten by sharks are relatively common, and the fact that turtles behave aggressively toward them is expected. However, the behaviors that turtles use to fend off sharks are not well documented. Rudloe (1979) reported that during an attack "turtles can sometimes chase off a shark by fleeing to the surface and beating their flippers, making a thunderous slapping noise that may be too much for the shark's delicate nervous system." Rudloe (1979) also wrote that "Archie Carr has told me about turtles blocking shark attacks by actually folding their flippers together under their plastron, bending their head down, and presenting their carapace as a shield."

Based on our encounter and those of others, adult leatherbacks use several different defensive behaviors when threatened, including ramming, biting, erratic swimming, thrashing on the surface, and swimming upside down on the surface. The survival benefits of ramming, biting, and erratic swimming are self-evident, but the value of swimming upside down and splashing on the surface is perhaps less clear. Swimming upside down on the surface may protect the vulnerable underside of a turtle from attacks lower in the water column. Splashing may deter an attack by a shark, but we can neither corroborate nor refute Rudloe's (1979) statement that the slapping noise made by a turtle is "too much for a shark's nervous system." Although leatherbacks may occasionally be preyed upon by sharks, a large healthy adult can obviously defend itself. Situations where leatherbacks are actually killed by sharks are probably exceptional and may occur mostly when a turtle is already wounded or sick.

Acknowledgments.—We thank George Balazs for his many helpful comments on a preliminary draft of the manuscript and for providing us with pertinent literature on leatherbacks. We gleaned much useful information in discussions with George Balazs, Thomas Fritts, Jack Woody, James Richardson, and Scott Eckert. We thank them for their input.

Herpetological Literature In The International Zoo Yearbook, Volumes 19-29 (1979-1990)

In 1979, Tryon (Herpetol. Rev. 10(3):87-90) listed 164 articles pertaining to herpetology published in the International Zoo Yearbook by the Zoological Society of London. The scope of the articles ranged from exhibits to disease and treatment, and contained much information not available elsewhere. As Tryon pointed out, the IZY tends to be a rather expensive publication and generally is not received by most libraries.

From the 1979 volume (#19) through the 1990 volume (#29), 117 articles related to reptiles and amphibians appeared in the IZY. For those individuals without access to the IZY, this listing, as with Tryon's review, serves as an introduction to the herpetological information published therein.

Articles are listed alphabetically by author and grouped in nine general categories in the following order: General Titles (13), Exhibits and Construction (8), Disease and Treatment (6), Amphibians (9), Turtles (22), Crocodilians (11), Lizards (21), Snakes (25), Tuataras (2).

GENERAL TITLES

A Reproducing Population Of *Trachemys scripta elegans* In Southern Pinellas County, Florida

Trachemys scripta elegans, the red-eared slider, occurs naturally northwest of Florida, from Indiana to Alabama west to New Mexico and extreme northeastern Mexico (Conant and Collins 1991). However, its widespread use in the pet trade promoted introduction of the subspecies at numerous localities in the eastern United States (Carr 1952; Dundee and Rossman 1989; Ernst and Barbour 1972; Harding and Holman 1990), including at least two in Florida: metropolitan Dade Co. (Wilson and Porras 1983) and in Lake Conway, near Orlando (Bancroft et al. 1983). Because of possible effects of introduced populations of *T. s. elegans* on native systems, it is important to identify such populations. The purpose of this report is to document the establishment of a breeding population of *T. s. elegans* in southern Pinellas Co., Florida.

Fox Hall Pond, Eckerd College, Pinellas Co., Florida was sampled for *T. s. elegans* using funnel traps (baited with sardines) periodically from 25 February 1991 to 8 May 1991. Carapace, plastron, and precloacal tail lengths, as well as weight were taken for all captured turtles. Sex was determined by plastron to cloaca length of the tail, or presence of the long claws of males (Gibbons 1988; Gibbons and Greene 1990). After marking, by notching of the marginal scutes of the carapace (Gibbons 1988), the turtles were released.

Two techniques were used to determine the reproductive status of the population. One female was dissected to determine if she was reproductively active and the population structure was examined for evidence of recruitment.

A population estimate was made using the Schnabel multiple census procedure (Everhart et al. 1953). These data were used with the total area of the pond (determined by aerial photo to be 1.17 ha) and mean weight of the turtles to estimate the density and biomass of the population.

A total of 16 *T. s. elegans* were captured 23 times during the ten week study period. Male, female, and juvenile turtles were represented by 11, 4, and 1 individuals respectively. Plastron length varied from 79.4 mm to 215.7 mm. The largest proportion of the sample, nine of sixteen individuals, ranged from 145 mm to 174 mm (Fig. 1).

Six males were above the minimum size for reproduction, as were the four females (Gibbons and Greene 1990). The ovaries of the smallest female were found to have a set of 28 well-developed follicles (average size 16.43 mm) and corpora albicantia, indicating reproductive activity.

The population estimate for *T. s. elegans* in Fox Hall Pond was 25.7 with a 95% confidence interval of 15 and 99, for which the bias was acceptable (Everhart et al. 1953). Using these data the population density and biomass were estimated as 20.9 turtles/ha and 13.5 kg/ha, respectively.

Presence of corpora albicantia and developing follicles provide direct evidence of reproductive activity in this population. Examination of population structure shows that the population seems to have an adequate number of reproductive sized individuals to maintain it. The presence of large juveniles and the finding of a hatchling skeleton on 14 September 1991, suggests that recruitment may be occurring. The absence of yearlings and hatchlings is probably a result of trap design (mesh size 26.4 mm) rather than absence of these age cohorts.

Populations of *T. s. elegans* were noted in southern Florida as early as 1966 (King and Krakauer 1966); however, established populations were not reported until much later (Wilson and Porras 1983). Population structure, presence of enlarged follicles, and corpora lutea were used to determine that a population of *T. s. elegans is* established in Lake Conway and adjacent areas near Orlando, Florida (Bancroft et al. 1983).

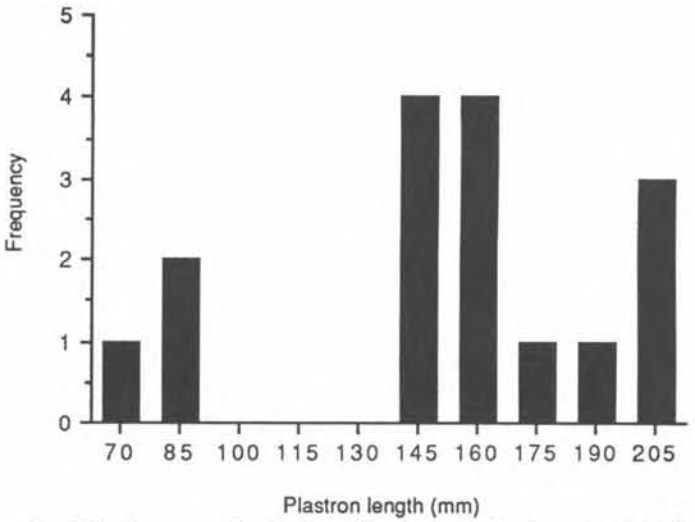

FIG. 1. Size frequency distribution of *Trachemys scripta elegans* in Fox Hall Pond, Pinellas Co., Florida.

Although competition with native fauna is a potential problem in Pinellas Co., genetic interference with native populations of *T. scripta* is not. *Trachemys scripta scripta* is native to Florida north of Gainesville and therefore allopatric with sites occupied by *T. s. elegans*. As Florida continues to develop, there exists a possibility that *T. s. elegans* will expand its range and intergrade with populations of *T. s. scripta*, as is occurring in Virginia (Mitchell and Pague 1990; Mitchell pers. comm.).

Acknowledgments.—I would like to thank Peter Meylan for his guidance in the design, for his comments on the many drafts of this paper, and for moral support. Tag Engstrom and Jennifer Garaway helped in constructing, setting, and checking the traps. I would also like to thank Joseph Mitchell for information about introgression in Virginia.

Activity Patterns Of *Algyroides fitzingeri* In Semi-natural Conditions

Algyroides fitzingeri is a lacertid lizard endemic to Corsica and Sardinia, where it occurs at elevations from 0 to 1600 m (Keymar 1988; Schneider 1981). Apart from habitat characteristics and diet (In Den Bosch 1986; Keymar 1988), the autecology of *Algyroides fitzingeri* is poorly known, possibly because of the elusive behavior of the adults. In this paper we report results of a short-term investigation of annual rhythm and daily activity patterns of *Algyroides fitzingeri* in semi-natural conditions.

Materials and Methods.—Five adult male and four adult female lizards, collected during May 1990 in Sardinia (Giara di Gesturi, 270 km SW of Nuoro), were transferred to Rome, and maintained under semi-natural conditions. Our outdoor enclosure measured 180 x 100 x 80 cm, with food (mealworms, grubs, small spiders, and worker ants), water, and subterranean shelters provided. Each specimen was numbered on the dorsal surface with harmless paint. Diel activity was studied by recording the number of male and female lizards moving on the surface (see Cooper et al. 1985). Individuals occupying subterranean shelters were not considered active; those partially under blocks with at least their heads exposed were considered active. Data were recorded at different intervals from June 1990 to May 1991, and sample size was 862. Statistical analyses were performed with an SAS computer package, all tests being two tailed. Our choice of statistical tests followed recommendations in Snedecor and Cochran (1980) and Zar (1984).

Information presented here should be interpreted as preliminary. In fact, we refer entirely to specimens maintained in an outdoor enclosure away from their normal environment, and it is difficult to evaluate the significance of the findings presented here.

Results and Discussion.—Male *Algyroides fitzingeri* were active from about 15 February to 10 December, while females were active from 10 March to 25 November. Annual duration of activity lasted longer in males ($\bar{x} = 301 \pm 5.43$ days) than in females ($\bar{x} = 261.75 \pm 6.99$ days) ($t = 9.51$, $df = 7$, $p = 0.00003$), following the general pattern of temperate zone reptiles (Duguy 1958; Saint Girons 1952, 1982). Both males and females fed from the end of March to 15-20 November. When not feeding, lizards spent most of their active time basking. Mating occurred from 10 to 30 April, while male-male agonistic behaviors—though detected with highest frequency during the mating period—were observed in different seasons (spring, summer, and autumn). The meaning of intrasexual interactions is not clear, as males were frequently seen quite close to, or in contact with, each other during thermoregulation without showing territorial or aggressive behavior.

Surface activity was diurnal (Fig. 1). Activity increased from first daylight until mid-day and decreased from mid-day until evening ($P<0.01$, Spearman correlation rank, with time of activity running against percent of lizards active). During early spring and late autumn, when night temperatures were low (ambient temperature < 10°C), daily emergence (normally after 0930 h) usually followed ground surface warming. In late spring and summer, when night temperatures remain high (ambient temperature > 15°C), lizard activity was initiated earlier in the morning (about 0730 h). The duration of daily activity was practically the same from June to the end of October (about 8-9 h), while it was restricted from March-May and from November-December (about 3-5 h). Some individuals were occasionally found above ground during sunny winter days; in these cases, however, less than 30%

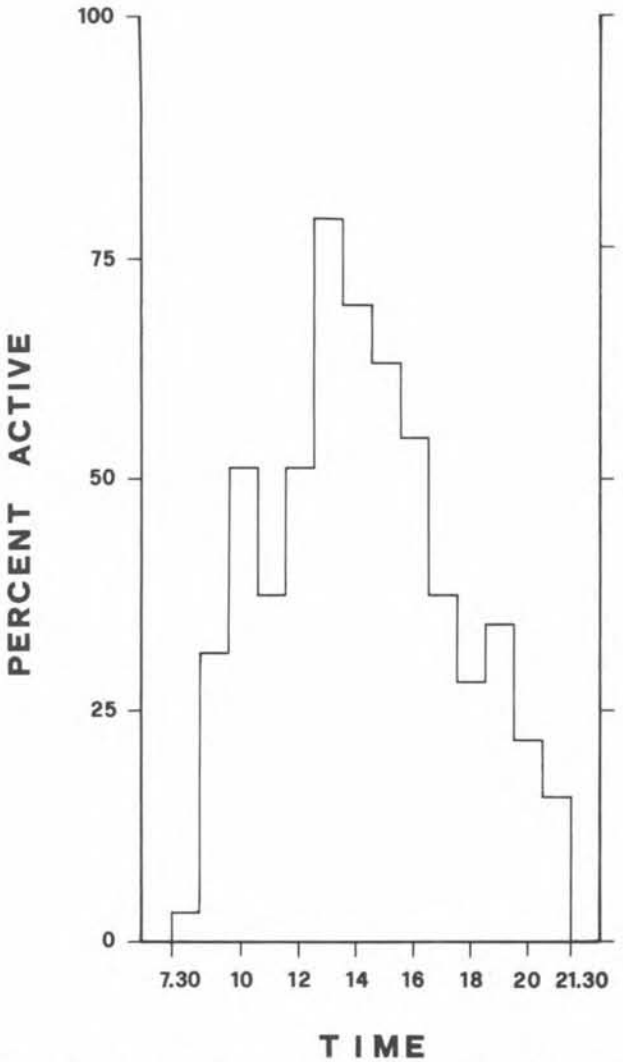

FIG. 1. Surface activity in *Algyroides fitzingeri* (European Standard Time).

of the population was active. Lizards basked more often ($P<0.01$, Mann-Whitney U-test) between 0830 h and 1130 h than during other activity hours; they frequently moved and caught prey during the warmest hours of the day. When *Algyroides* were basking, they often disappeared for brief periods either because they utilized multiple basking sites, or because they moved into the shade to bring down their body temperature. This type of basking behavior has been observed in other species of lacertid lizards (Avery 1979). Male *Algyroides* move more often than females during the mating period, but the percentage of active males (i.e., those exposed at the surface) was not significantly higher than that of females. Lizards were not found active during rain or on windy days. A few specimens were sometimes found basking during cool (air temperatures = 12-14°C) but sunny days, especially in early spring or late autumn.

In conclusion, a unimodal diel activity pattern, with a major peak between 1230 h and 1400 h, was observed in these lizards. This general pattern has been observed in lizards inhabiting cool climates, while bimodal patterns have been detected in lizards occurring in hot climates (Busack and Visnaw 1989; Cooper et al. 1985; Huey et al. 1977; Pianka 1973; Tinkle 1967). Thermoregulatory behaviors were concentrated in early activity hours, and lizards were active from 3 h to 8-10 h per day depending on the environmental temperatures. However, this did not necessarily imply that each individual was active for the whole period.

Keymar (1988) reported that free-living *Algyroides* emerge earlier in the morning than sympatric *Podarcis sicula* and *P. tiliguerta*. Moreover, sympatric *Podarcis* usually bask at temperatures higher than those preferred by *Algyroides*. Differing thermal requirements might be due to the uniform dark-brown dorsal color of *Algyroides* (Keymar 1988), which permits better absorption of radiation. Diel activity can be significantly modified in indoor terrariums having experimental daylight intervals. We were able to prolong the activity period of captive *Algyroides* up to 20 h by maintaining them in constant daylight. This drastic change of daylight conditions strongly modified both diel and annual activity in these lizards. Specimens maintained under these conditions did not show any sexual activity in spring and did not copulate. Specimens that did not hibernate during the winter period showed no sexual activity either.

Acknowledgments.—We thank A. Berardo for his statistical advice, Stephen Busack, G. A. Middendorf, and one anonymous referee for having greatly improved the manuscript. Moreover, we are indebted to Pam Lopez and Laurie Vitt for responding to our bibliography requests. Claudio Anibaldi provided expert technical advice in the construction of the lizard enclosure.

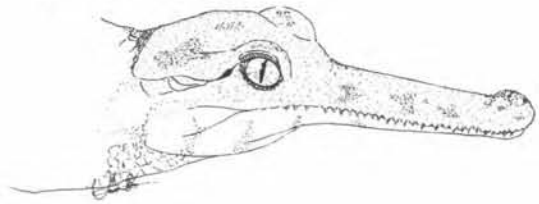
POINT OF VIEW

Credit Where Credit Is Due: A Plea To Authors And Editors

It is becoming increasingly common in herpetological publications to omit individual acknowledgment, by name, of institutions that provided specimens or other resources for the study. I believe two factors are responsible for this trend: the laudable desire of editors to maximize page space for results, and general adoption of the "standard" museum acronyms referenced in Leviton et al. (1985). Whatever the reasons, omission of institutional acknowledgments has a potential for negative impact on systematic herpetology collections and their bases of support.



One of the strongest justifications for continued or increased financial support of a collection is quantity of use. Collection use can be measured indirectly in numbers of loans, exchanges, research visitors, or students. But a direct and quantitative measure is the number of publications that acknowledge use of the collection or associated resources. Museum administrators and granting agencies have an insatiable hunger for such numbers, which can be used to justify financial decisions. Those decisions, at the individual collection level, can translate to "life or death."

I am not pleading for acknowledgment of systematic collections' contributions to herpetology on the basis of either courtesy or tradition. If saving page space is of primary importance, then acknowledgment of individual curators or collection managers can be eliminated. After all, answering the mail, copying data, and packing loans are part of the job and merit no special recognition. But identification of contributing institutions is indispensable as long as those who hold the purse strings demand repeated demonstration of each collection's relevance.

HERPETOLOGICAL HUSBANDRY

Captive Maintenance Of The Primitive New Zealand Frog, *Leiopelma hochstetteri*

The New Zealand endemic frog, *Leiopelma hochstetteri*, is of interest mainly because of its many primitive morphological features. The species' range consists of at least eight disjunct regions on the North Island and adjacent Great Barrier Island of New Zealand (Bell 1982; Green and Tessier 1990; Pickard and Towns 1988). The frogs inhabit cool streams and rivulets in undisturbed native forest (Robb 1980; Stephenson and Stephenson 1957) and because of their dwindling habitat (Bell 1985), the species is under protection by the New Zealand Department of Conservation. In 1987 and 1989, one of us (DMG) collected live frogs and we attempted to simulate their natural habitat in the laboratory seeking breeding in captivity.

We have kept some of our frogs for three years in specially modified "riffle" tanks, which we constructed (Sharbel and Green 1989). The tanks are similar to a stream vivarium described by Mattison (1987), but are probably more efficient and easier to maintain (Fig. 1). Within each large aquarium, an artificial cascading stream bed was fabricated out of fiberglass. On this foundation, we placed rocks of various sizes and sand. These provide the same type of substrate found in natural streams. An external aquarium pump provides the stream flow and water filtration. The filter intake is at the lower end of the tank and the outlet is positioned at the upper end of the tank so that the water can flow down the stream bed. The rocks provide a variety of hiding places and microhabitats. Within the tank there are relatively dry areas on the tops of rocks or in protected areas next to the simulated stream, an open water pool at the lower end of the tank, and flowing water of variable intensities on the different levels. The pumps are cleaned once a month and the charcoal filters are changed every two months.

We have constructed four tanks, which are kept in a walk-in environmental chamber in our lab (Fig. 2). This provides the necessary temperature and photoperiod control. In the wild, the streams in which the frogs live were never recorded above 20°C, even in midsummer. The frogs are tolerant of cool temperatures but not high ones. Accordingly, the temperature within the chamber is regulated to 17°C. It may be possible to achieve the same net result with tanks kept at room temperature by using refrigerated water pumps. The chamber is illuminated by a single "natural daylight" fluorescent tube on a 12-h photoperiod. We have not monitored the physical and chemical properties in the aquaria.

We are housing frogs from three separate populations. In their natural habitats, *L. hochstetteri* hide under rocks or in crevices beside streams during the day (Bell 1982; Tessier et al. 1991) and the frogs of our colony exhibit similar behavior. No evidence of aggression or territoriality has been noted and as many as five individuals have been found hiding under one rock. Individuals show some fidelity to their individual hiding places, as in nature, and an individual usually will be found under the same rock day after day. The frogs also are sometimes found submerged in the lower ends of the tanks. Oddly, for semi-aquatic animals, they are not particularly good swimmers and employ a sort of "dog-paddle" motion in the water instead of the more commonly-known anuran "frog-kick."

The frogs become active during the evening when they evi-

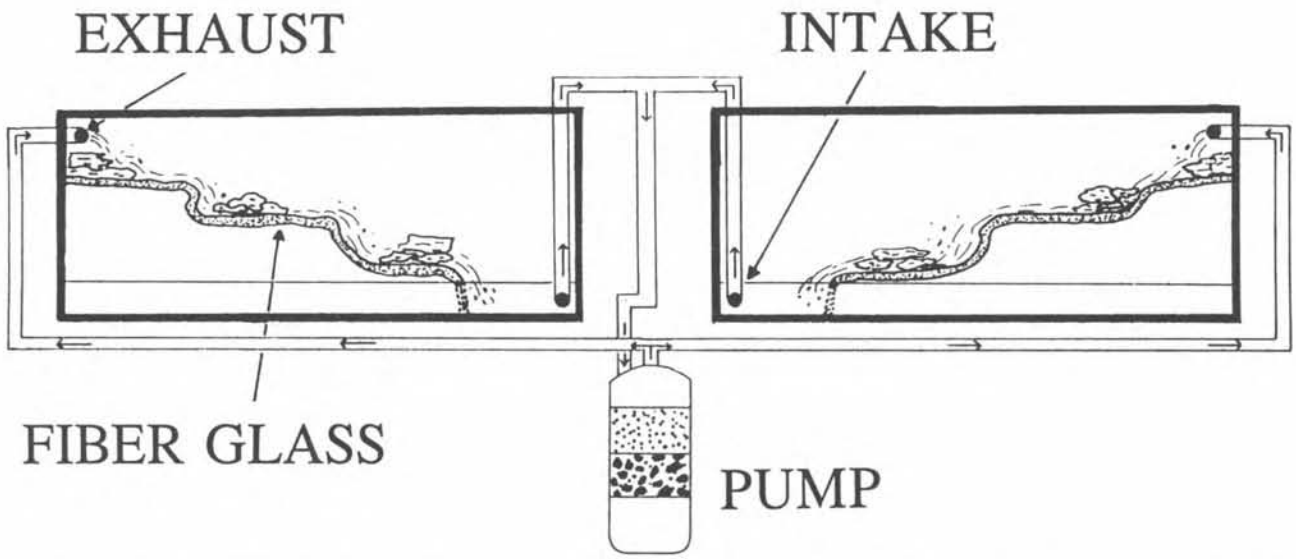

FIG. 1. Schematic diagram showing the configuration for two riffle tanks connected to a singe pump. Arrows show direction of water flow. (From Sharbel and Green 1989).

dently forage for food. They are fed second and fourth instar crickets (Fluker's Cricket Farm, Inc.) once weekly. The crickets are fed high protein rat chow for a day before being fed to the frogs so that their guts might contain many extra nutrients. No other dietary supplements have been given to the frogs. Introduced crickets can remain alive for up to one week in the tanks.

From an original stock of 28 frogs, we have euthanized 11 frogs for research purposes and four frogs have died, apparently from disease. Two of those may have died from kidney dysfunction or a form of subcutaneous lymphatic edema. These individuals were bloated with fluid and appeared unable to control their physiological water balance. Necropsies of these animals revealed enlarged, abnormally whitened kidneys. One individual exhibited abnormal neuromuscular control and was euthanized.

The frogs have shown significant growth over the two years of captivity. Our attempts at individually marking frogs have been unsuccessful so all we can present are average lengths of the frogs in each tank. The frogs from Great Barrier Island averaged 35.7 mm (SVL, N = 8) in January, 1989, while in January, 1991 they averaged 38.7 mm SVL (N = 5). The Tokatea Ridge frogs averaged 33.5 mm SVL (N = 10) in 1989 and 34.8 mm SVL (N = 4) in 1991. Frogs from Toatoa were 31.6 mm SVL (N = 10) in 1989 and 35.6 mm SVL (N = 4) in 1991. This information underestimates the growth of our frogs since most of the frogs used for research were the larger adults. Perhaps more significantly, when we caught the frogs from Toatoa, none was adult. Since that time several have reached sexual maturity and developed secondary sexual characteristics.

FIG. 2. Artificial stream bed in riffle tank (with frog *in situ*) showing fiberglass channels directing water flow. Rocks and broken clay flower pots provide hiding places.

We have not attempted to simulate seasonal variation in day/night cycle but the frogs still appear to follow an annual reproductive cycle. In January of both 1990 and 1991, some of the largest of our females became gravid. So far, however, the frogs will not amplex and females will not lay eggs on their own. To remedy this, we have attempted to stimulate breeding artificially with hormones. With partial success, we have given a selected gravid female an intraperitoneal (I.P.) injection of 50 units human chorionic gonadotropin (HCG; Sigma) over two days, followed on day three with 5 µg (I.P.) of luteinizing hormone releasing hormone (LHRH; Sigma) analogue (Barnabe and Barnabe-Quet 1985). At the same time, a male from the same tank was given 50 units HCG I.P. A dose of 10 µg of LHRH given to another gravid female resulted in apparent overstimulation leading to death. We have noticed no adverse effects resulting from the HCG injections in either sex. With the hormone treatments, we have been able to induce amplexus and even egg laying, but so far no eggs have developed. We cannot say at this time whether the lack of hatching success has been because the eggs were not fertilized or because environmental conditions were incorrect. Despite known information about the natural history of the frogs (Bell 1985; Turbott 1949), including general information about breeding habits, precise environmental parameters necessary for successful egg incubation of *L. hochstetteri* are not known. The reproductive biology of *L. hochstetteri* is quite different from the fully terrestrial species, *L. archeyi* and *L. hamiltoni*, which have been successfully bred in captivity (Bell 1982, 1985).

LIFE HISTORY NOTES

Instructions for contributors to Life History Notes appear in volume 23, number 2.

CAUDATA

PLEURODELES WALTL (Iberian Newt). **ALBINISM**. An adult male *Pleurodeles waltl* was captured 10 April 1988 in a natural pond (Bassa de Montredons, Rasquera, Tarragona Province, Spain, UTM 31TBF9936) at 280 m elevation. The normal color pattern of this species is brown or olive green. The belly is white or pink with grey spots (García-París 1985. Los anfibios de España. Min. Agri. Pes. y Alim. Madrid, 287 pp.). The general color of this specimen was yellowish with grey patches. Limbs and tail were reddish because of the blood vessels seen through the transparent skin. The upper head, the dorsal trunk, and both sides of the tail were dark grey owing to a local accumulation of pigment (Fig. 1). The eyes were black for the same reason. The belly was homogeneous yellowish without spots.

This is an apparent example of a partial albino with xanthophores (Drykacz 1981. SSAR Herp. Circ. 11, 31 pp.). We assume the animal is amelanic because the eyes have red pupils. The pigmented patches of skin may be due to local concentrations of xanthophores (Bagnara et al. 1978. Amer. Zool. 18:301-318).

The animal is being maintained alive in captivity and pigmentation has not changed since time of capture. This is the first report of albinism in this genus.

FIG. 1. Partial albino *Pleurodeles waltl*, dorsal view.

ANURA

ELEUTHERODACTYLUS COQUI (Puerto Rican Coqui). **PREY**. Most frogs are insectivorous and too small to prey on vertebrates, but there are reports of large frogs feeding on smaller vertebrate prey (Greene 1988. Antipredator mechanisms in reptiles. *In* C. Gans and R. B. Huey (eds.), Biology of the Reptilia, Volume 16, Ecology B. A. R. Liss, New York, pp. 1-152; Branch. 1976. J. Herpetol. 10(3):266-268). Here we report on an *Eleutherodactylus coqui* feeding on a lizard, *Anolis evermanni*. *E. coqui* is a small leptodactylid frog with a maximum SVL of 52 mm; it has been characterized as an extreme sit-and-wait nocturnal predator (Woolbright and Stewart 1987. Copeia 1987(1):69-75) that preys mostly on arthropods (Woolbright 1991. Biotropica 23(4a):462-467) .

The frog, an adult female *E. coqui* (SVL = 43 mm), was found inactive during the day on 14 April 1991 at the Bisley area of the Luquillo Experimental Forest (LEF) of Puerto Rico, under the loose bark of a dead branch of a motillo (*Sloanea berteriana*) at ca. 30 m above the ground. The frog had a large mass in the stomach region that could be seen through the ventral body wall. We forced the frog to regurgitate its stomach contents and found a partially digested juvenile *A. evermanni* (SVL ca. 43 mm) and a scarabid beetle, *Diaprepes abbreviata*. The fact that the frog was able to feed on an anole that was equal to its own SVL is remarkable, not only for the size of the anole but also for the strong defenses that anoles can present when they are attacked by a predator.

Specimens were deposited in the Museum of Biology, University of Puerto Rico, Rio Piedras (UPRRP 5746 *E. coqui*; UPRRP 5747

A. evermanni). We thank J. A. Rodriguez-Robles for identifying the beetle and reviewing the manuscript and Roman Dial for collecting the frog.

Submitted by **MANUEL LEAL** and **RICHARD THOMAS**, Department of Biology, P. O. Box 23360, University of Puerto Rico, Rito Piedras, Puerto Rico 00931-3360, USA.

CROCODYLIA

ALLIGATOR MISSISSIPPIENSIS. (American Alligator). **NEST MATERIAL**. Female alligators incubate their eggs in cone shaped nests. Nests usually consist of herbaceous vegetation and soil that are scraped together at the nest site. On 11 September 1990, two of the authors (LJH and DND) observed three unusual alligator nests at the Alico Company property, R.29E, T.45S, Hendry Co., Florida. The nests were built on the edge of a levee that contained an abandoned railroad bed of granite stones. Each conical nest was composed mainly of granite cobble (ca. 5 cm diam) with some plant material (*Andropogon* spp.)(Fig. 1). All three nests were similar in size (ca. 100 cm diam x 40 cm high) and located within a span of 300 m. The levee vegetation was primarily willow (*Salix* spp.), wax myrtle (*Myrica cerifera*), and scattered grasses (*Andropogon* spp.). The levee was bounded on both sides by emergent marsh predominantly vegetated with pickerelweed (*Pontederia cordata*).

The eggs had been previously collected from these nests as part of the Florida Game and Fresh Water Fish Commission's alligator management program. The eggs had been taken to an alligator farm for incubation, and produced viable hatchlings (J. Worden, pers. comm.). Data on clutch size and hatch rate are unavailable.

We have observed other alligator nests where inorganic objects (e.g., rocks, trash) have been incorporated, but never to this extent.

We thank P. E. Moler and T. E. O'Meara for reviewing the manuscript.

FIG. 1. The nest of an *Alligator mississippiensis* consisting primarily of granite stones.

TESTUDINES

CHRYSEMYS PICTA PICTA (Eastern Painted Turtle). **PREDATION.** Previous accounts of predation by invertebrates on reptiles and amphibians focused primarily on lizards and frogs (Bauer 1990. Herpetol. Rev. 21:83-87; Hinshaw and Sullivan 1990. J. Herpetol. 24:196-197; McCormick and Polis 1982. Biol. Rev.57:29-58), but crabs regularly prey on sea turtle hatchlings (Stancyk 1982, *In* K. Bjorndal (ed.) Biology and Conservation of Sea Turtles, pp. 139-152). Here I report predation by invertebrates on juvenile freshwater turtles. Two hatchling and one small juvenile *Chrysemys picta* (CL 20-30 mm) were observed being attacked by large (40-50 mm) giant water bugs (Hemiptera: Belostomatidae) on three different occasions during early summer 1990. These attacks occurred along the vegetated margins of a shallow pond (3 ha) at the Patuxent Wildlife Research Center, Prince Georges Co., Maryland. In all three cases, the water bugs firmly grasped the turtles' carapace from the top with their legs and inserted their proboscis at the base of the turtles' necks beneath the anterior rim of the carapace. Only one of the turtles appeared alive when discovered, and it was not actively resisting or attempting to escape. About 30 min later, the water bug was on the now dead turtle and still had its proboscis inserted. Although hatchling turtles are vulnerable to many predators, most studies have focused on vertebrates. My observations suggest that large aquatic invertebrates also may be an important factor in juvenile turtle mortality.

Submitted by **STEVE W. GOTTE,** U. S. Fish and Wildlife Service, National Museum of Natural History, Washington, D.C. 20560, USA.

SERPENTES

COLUBER CONSTRICTOR (Black Racer). **PREDATION.** Annual mortality of adult *Coluber constrictor* is known to vary from 21-46% among three populations (Brown and Parker 1984. *In* R. A. Seigel, L. A. Hunt, J. L. Knight, L. Malaret, and N. L. Zuschlag (eds.), Vertebrate Ecology and Systematics, a Tribute to Henry S. Fitch. Univ. Kansas Mus. Nat. Hist. Special Publ. No. 10, pp. 13-40; Fitch 1963. Univ. Kansas Publ. Mus. Nat. Hist. 15:351-468; Rosen 1991. Copeia 1991:897-909), but the specific sources of adult mortality are poorly known. During the period 20 July - 18 October 1989, we radiotracked ten adult *C. constrictor* on the Savannah River Site near Aiken, South Carolina. Two snakes (20%) suffered predation in this period. One snake (male, 83 cm SVL, 140 g) was released on 28 July and monitored daily as it moved around and through a Carolina bay. On 3 August, it was eaten by a 112 cm, 420 g female *Lampropeltis getulus*. A second *C. constrictor* (female, 90 cm, 164 g), was released on 28 July. Over the next nine days it moved >1.2 km from the original point of capture. On 6 August, the snake was tracked to a mixed pine/hardwood forest where it was found in a pre-shedding opaque condition coiled in an abandoned bird nest 6 m up in a pine tree. When the nest was checked the following morning, the snake's head and anterior part of its body were missing.

Mortality in our approximate 90-day study was similar to that in Fitch and Shirer's (1971. Copeia 1971:118-128) radiotelemetric

study of *C. constrictor* in which two of 12 (17%) snakes suffered predation over a period of <102 days. If the 90-day mortality in our study is adjusted up to an annual rate (Krebs 1989. Ecological Methodology. Harper & Row, New York, 654 pp.), the value obtained (60%) is greater than annual mortality observed in three natural populations. The calculation of annual mortality from mortality observed in a restricted part of the year assumes that mortality is constant over the entire year, an assumption which may not be true in *C. constrictor* (Brown and Parker 1984. op. cit.). However, the calculation strongly suggests that the 20% mortality observed over 90 days was, in fact, high.

Although these data are limited, they suggest that significant mortality of adult *C. constrictor* may result from predation, despite these snakes being relatively large, fast-moving, alert, and occasionally aggressive (Fitch 1963. op. cit.).

Small snakes with implanted transmitters may suffer high rates of predation in the short term perhaps as a result of the increased mass burden of the transmitter (Plummer 1990. J. Herpetol. 24:327-328). In this study, the ratio of transmitter mass/body mass was less than 5%.

We thank J. Haskins for assisting in radiotracking. This work was supported by contract DE-AC09-76SROO-819 between the U.S. Department of Energy and the University of Georgia's Savannah River Ecology Laboratory.

Submitted by **MICHAEL V. PLUMMER** and **JUSTIN D. CONGDON**, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29801, USA. Present address (MVP): Department of Biology, Harding University, Searcy, Arkansas 72143, USA.

LAMPROPELTIS PYROMELANA (Sonoran Mountain Kingsnake). **PREDATION.** As part of a continuing study of Mexican spotted owl (*Strix occidentalis lucida*) diet in Arizona and New Mexico, I identified the skeletal and epidermal remains of vertebrate and invertebrate prey items, primarily from regurgitated pellets. Mexican spotted owls feed on a variety of mammals, birds, reptiles, and arthropods, although mammals make up the bulk of their diet (>90% biomass; Duncan and Sidner 1990. Great Basin Nat. 50:197-200; Ganey 1988. M.S. thesis, Northern Arizona Univ., Flagstaff; E. D. Forsman, pers. comm., 1990; R. B. Duncan, this study and unpubl. data). Snakes are considered a rare prey item of spotted owls (Ross 1989. Wisconsin Endangered Species Res. Rep. 59). Ross (op. cit.) compiled published accounts of spotted owl diet containing reptiles and amphibians, in which only one snake, the western terrestrial garter snake (*Thamnophis elegans*), was documented.

In this study of spotted owl prey, reptiles accounted for <0.5% of the total number of prey items (N = 2557) and <0.2% total biomass. Among the catalogued reptiles, only one snake and 12 lizards were identified (Duncan, unpubl. data). The Sonoran mountain kingsnake was identified from a pellet sample that was regurgitated in July 1989 in the Huachuca Mountains, Cochise Co., Arizona beneath a roost in a steep canyon (elev. 1737-2134 m) in montane riparian woodland bordered by montane conifer forest and Madrean Evergreen Woodland (Brown 1982. Desert Plants 4:1-342). The specimen has been deposited at the USFS, Southwest Regional Office, Albuquerque, New Mexico, as part of a comparative collection of Mexican spotted owl prey items.

This manuscript benefited from the editorial comments of F. W. Reichenbacher and J. D. Taiz, and was written while the author was supported by a professional services contract from the U. S. Forest Service (USFS), Southwest Region.

MASTICODRYAS PLEII. (NCN). **ANTIPREDATOR BEHAVIOR.** During field work in the northwestern region of the Peninsula de Paraguaná, north-midwestern Venezuela, we observed a *Mastigodryas pleii* crawling slowly on the ground within a small patch of vegetation. When disturbed, the snake attempted to escape by crawling rapidly to a group of *Opuntia wentiana* (Cactaceae), where it stopped under one the plants. It then began slowly to climb the spines of the cactus until it reached the uppermost pad (ca. 1.3 m above ground). The snake then remained immobile but alert for 1-2 min before it was trapped.

In another instance, near Cabo San Román (northernmost extreme of the Peninsula de Paraguaná), another *M. pleii* displayed similar behavior. The second snake was discovered trapping a lizard (*Ameiva bifrontata*) under an *O. wentiana*. The snake tried to escape from the collector by climbing into the spiniest part of the cactus and it also then stayed quiet but alert.

We infer that this behavior could reflect a defensive tactic in response to medium- to large-sized terrestrial or avian predators. The *O. wentiana* pads detach very easily. The spines penetrate the skin readily, are very difficult to remove, and cause intense pain.

Submitted by **ABRAHAM MIJARES-URRUTIA** and **ALEXIS ARENDS R. CIEZA-UNEFM**, Apartado 7506, Coro 4101-A, Venezuela.

OPHRYACUS UNDULATUS (Horned Pit Viper). **DIGESTIVE DISTURBANCE.** *Ophryacus undulatus* is a semiarboreal species distributed in the Sierra Madre del Sur of Guerrero and Oaxaca, west-central Veracruz, the Mixteca region in Oaxaca (Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Comstock Publ. Assoc., Cornell Univ. Press, Ithaca, New York, 425 pp.), and Hidalgo (O. Flores, pers. comm.).

An adult male *O. undulatus*, SVL = 536 mm (MZFC-04825), was collected on 14 July 1990 at El Portrero, Tenango de Doria, Hidalgo. This snake had an intestinal obstipation, which dissection revealed to be a skull of the Mexican vole (*Microtus mexicanus*). Part of the skull, especially the broken zygomatic arches, projected into the wall of the large intestine, obstructing free passage of feces. Scales and bones of one *Sceloporus grammicus* (mesquite lizard) that was ingested in captivity were also found.

A detailed external macroscopic examination of the affected area revealed strong swelling of the intestinal wall and although the wounds caused by the pieces of the zygomatic arches were healed over, they still contained the whole bone mass.

Information regarding this kind of perturbation is known only from captive animals (e.g., *Boa constrictor*) and more often in terrestrial chelonians (Frye 1981. Biomedical and Surgical Aspects of Captive Reptile Husbandry. Veterinary Medicine Publ. Co.). Our observation suggests that misdigested prey items in natural conditions may have potentially lethal consequences.

We thank Arturo González, Adolfo Navarro, Oscar Flores, H. M. Smith, and Jack Sites, Jr. for their comments on this manuscript, Mario Mancilla for help in the field, and Livia León and Gabriel Pérez for identifying the mouse. Financial support was provided by the Direccion General de Apoyo al Personal Academico (DGAPA) project IN201789.

REGINA ALLENI (Striped Crayfish Snake). **PREDATION**. Godley (1982. Florida Field Nat. 10:31-36) reported on seven species of predators of *Regina alleni*, two of which were avian. Here, I report on a third avian predator. On 19 April 1991, while checking drift fences in a cypress dome during a herpetofaunal survey of the Lake Thonotosassa watershed (Florida, Hillsborough Co.) I flushed an adult *Buteo lineatus* (red-shouldered hawk) from among the sparse forb layer of the dome floor. The hawk flew about 5 m from the flush site, perched on a lateral cypress limb, and observed my movements near the flush site. At the flush site I found a female *R. alleni* (UF 91640, SVL = 385 mm, tail length = 99 mm, live mass = 40 g). The snake was incapacitated due to trauma of the head but was not dead. A nest with juvenile hawks was in the vicinity and I assume that the snake was to be fed to them. Ross (1989. Wisconsin Endangered Species Res. Rep. 59) listed five species of snakes as prey items of *B. lineatus*, three of which were natricine. This is the first report of *R. alleni* as a prey item of any raptor.

Submitted by **JAMES C. GODWIN**, Florida Game & Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

TRIMORPHODON BISCUTATUS (Lyre Snake) **PREDATION FATALITY**. On 12 November 1991 at 1130 h, we observed an adult male *Trimorphodon biscutatus* capture a large adult male *Ctenosaura pectinata* on the ground. The general habitat was tropical dry forest at the Biological Field Station "Chamela", Jalisco (19° 30' N; 105° 03' W). The snake measured 1500 mm (SVL), 250 mm tail length (TL), 4.5 cm head width, and weighed 1183 g (after removal of prey). The lizard measured 300 mm SVL, 460 mm TL, and weighed 405 g. The snake observed the lizard for 15 min before capturing it. The snake constricted the lizard at the shoulders and neck and then ingested it head first. Capture and ingestion occurred from 1145 to 1330 h. The snake stayed in the same place after ingesting the lizard, moving its body. After 20 min it stretched, turned belly up, and died. Dissection revealed that the esophagus and stomach were ruptured by the spines of the lizard.

We thank Stephen Corn and Miriam Benabib for their comments on this note.

Submitted by **AURELIO RAMÍREZ-BAUTISTA** and **ZEFERINO URIBE**, Laboratorio de Herpetología, Departamento de Zoología, Instituto de Biología, UNAM. AP. 70-153, México 20, D.F. 04510 México.

TYPHLOPS SCHINZI (Beaked Blind Snake). **MAXIMUM SIZE**. On 26 March 1990 at 2045 h, a *Typhlops schinzi* was collected alive on a paved road 48.1 km east of Springbok, South Africa. The snake measured 283 mm total length. This exceeds the previous record of 255 mm reported by Roux-Esteve (1975. Recherches sur la morphologie, la biogeographie et la phylogenie des Typhlopidae d'Afrique. Bull. I.F.A.N. A36, 428-508.).

On 31 March 1990, a second specimen of *T. schinzi* was collected at 1950 h alive on a paved road 28 km east of Luderitz, Namibia (formally South West Africa). This specimen was slightly larger than the aforementioned snake and measured 293 mm total length. Both snakes have been preserved and deposited in the vertebrate collection of the Carnegie Museum of Natural History (CM 119300 & 119342).

THE CHELONIAN RESEARCH FOUNDATION
Announces the Establishment of the Linnaeus Fund

And Solicits Chelonian Research Proposals for its

ANNUAL TURTLE RESEARCH AWARDS

- Awards to be granted to individuals or nonprofit organiztions for specific turtle research projects, with either partial or full support as funding allows
- Priority given to projects concerning freshwater turtles, but tortoise and marine turtle research proposals also considered
- Priority given sequentially to the following general research areas:
  - Taxonomy and Systematic Relationships
  - Distribution and Zoogeography
  - Morphology and Natural History
  - Other Turtle Research

Priority given to projects that demonstrate potential relevance to the scientific basis of Chelonian Biodiversity and Conservation Biology. Award recipients agree to publish at least partial or summarized results of the supported research in a CRF - sponsored publication.

Application Deadline: 1 November 1992

JOB ANNOUNCEMENT

Six seasonal technical positions with the Missouri Department of Conservation will be available from 1 March – 31 October, 1993. Technicians will construct herp arrays and collect Ozark forest herpetofauna caught in arrays. Work will include marking herpetofauna for possible recapture. This research is part of a larger project to examine the effects of even- and uneven-aged forest management on Ozark forest plant and animal communities. The pay is $4.69/hour for 40 hours per week. Housing, utilities, and vehicles in Ellington, Missouri will be provided. To receive an official application, please send cover letter and résumé to Rochelle B. Renken, Missouri Department of Conservation, 1110 South College Avenue, Columbia, Missouri 65201 or call 314-882-9880. Interviews will be conducted by phone or in person. Applications must be received by 1 November 1992.

GYRINOPHILUS PORPHYRITICUS (Spring Salamander). USA: TENNESSEE: Cannon Co: seepage area associated with springhead of East Fork of the Stone River in Dug Hollow (35°51'0"N, 85°57'30"W). 7 March 1991. B. T. Miller. Verified by D. E. Metter. Middle Tennessee State University (MTSU 49C). New county record; extends the known distribution into the eastern Highland Rim outliers located within the Outer Central Basin of Tennessee (Redmond 1985, A Biogeographic Study of Amphibians in Tennessee, Doctoral Diss., Univ. Tennessee, Knoxville, 290 pp.).

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: ILLINOIS: Perry Co: NW 1/4 Sec. 14, T6S, R3W, Pyramid State Park. 12 March 1991. M. Bavetz, R. Flick & H. Moeller. Verified by Ronald A. Brandon. Southern Illinois University Department of Zoology Collection (SIUC H4060). County record (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **MARK J. BAVETZ**, **ROBERT W. FLICK**, and **HARRY MOELLER**, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA.

NOTOPHTHALMUS VIRIDESCENS VIRIDESCENS (Red-spotted Newt). USA: KENTUCKY: Campbell Co: Melbourne; Withamsville Quadrangle, 39°01'40"N, 84°22'25"W. 16 April 1992. Paul J. Krusling, Jeffery G. Davis & Dean McCoy. Verified by John W. Ferner. Cincinnati Museum of Natural History (CMNH 3539–3546). New county record.

Submitted by **PAUL J. KRUSLING**, Department of Herpetology, Cincinnati Museum of Natural History, Frederick and Amey Geier Research and Collections Center, 1720 Gilbert Avenue, Cincinnati, Ohio 45202, USA.

PLETHODON DUNNI (Dunn's Salamander). USA: WASHINGTON: Grays Harbor Co: E bank of North River, 1.6 km N Grays Harbor-Pacific Co. line, Sec. 7, T16N, R10W. 14 April 1991. A. G. Wilson, Jr. Verified by John A. Hall. Charles R. Conner Museum, Washington State University, Pullman (CM 92–1). New county record; extends the range northward. (Nussbaum, Brodie, and Storm 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press, Moscow. 332 pp.).

Submitted by **ALBERT G. WILSON, JR.**, Department of Zoology, Washington State University, Pullman, Washington 99164–4236, USA, **KELLY R. MCALLISTER**, Washington Department of Wildlife, Nongame Program, 600 North Capitol Way, Olympia, Washington 98504, USA, and **JOHN H. LARSEN, JR.**, Department of Zoology, Washington State University, Pullman, Washington 99164–4236, USA.

PLETHODON GLUTINOSUS (Northern Slimy Salamander). USA: KENTUCKY: Campbell Co: 1.1 mi. NW Hawthorne; Alexandria Quadrangle, 38°59'15"N, 84°26'05"W. 16 April 1992. John W. Ferner. Verified by Paul J. Krusling. Cincinnati Museum of Natural History (CMNH 3529). New county record.

Submitted by **JOHN W. FERNER**, Department of Herpetology, Cincinnati Museum of Natural History, Frederick and Amey Geier Research and Collections Center, 1720 Gilbert Avenue, Cincinnati, Ohio 45202, USA.

PLETHODON VANDYKEI (Van Dyke's Salamander). USA: WASHINGTON: Thurston Co: W bank of Skookumchuck River, 0.6 km N Thurston-Lewis Co. line, Sec. 20, T15N, R2E. 6 June 1991. A. G. Wilson, Jr. Verified by Richard L. Wallace. Charles R. Conner Museum, Washington State University, Pullman (CM 91–581). New county record; extends westward the Cascade Mountains range of the salamander (Nussbaum, Brodie and Storm 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press, Moscow, 332 pp.).

Submitted by **ALBERT G. WILSON, JR.**, Department of Zoology, Washington State University, Pullman, Washington 99164–4236, USA, **KELLY R. MCALLISTER**, Washington Department of Wildlife, Nongame Program, 600 North Capitol Way, Olympia, Washington 98504, USA, and **JOHN H. LARSEN, JR.**, Department of Zoology, Washington State University, Pullman, Washington 99164–4236, USA.

RHYACOTRITON OLYMPICUS (Olympic Salamander). USA: WASHINGTON: Thurston Co: W bank of Skookumchuck River, 0.6 km N Thurston-Lewis Co. line, Sec. 20, T15N, R2E. 6 June 1991. A. G. Wilson, Jr. Verified by David B. Wake. MVZ 218219. New county record; extends northward the Cascade Mountains range of the salamander (Nussbaum, Brodie, and Storm 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press, Moscow. 332 pp).

Submitted by **ALBERT G. WILSON, JR.**, and **JOHN H. LARSEN, JR.**, Department of Zoology, Washington State University, Pullman, Washington 99164–4236, USA.

SIREN INTERMEDIA (Lesser Siren). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 10, R22E, T20S. 22 March 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80577. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida, Part 3. The Amphibians., Windward Publ., Inc., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

SIREN LACERTINA (Greater Siren). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 10, R22E, T20S. 15 March 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80578. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida, Part 3. The Amphibians, Windward Publ., Inc., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

ANURA

ARCOVOMER PASSARELLII (NCN): BRASIL: SÃO PAULO: Ubatuba: Parque Estadual da Serra do Mar, Núcleo de Picinguabe (ca. 23°23'S, 44°50'W). 1–3 November 1991. E. C. P. Pombal & J. P. Pombal, Jr. Verified by Ivan Sazima. Museu de História Natural, Universidade Estadual de Campinas (ZUEC 9174–9175). First documented record for the state of São Paulo, extending the distribution southward. Published distribution of the species is Espírito Santo and Rio de Janerio states, southeastern Brazil (Frost 1985, Amphibian Species of the World. A Taxonomic and Geographical Reference. Allen Press, Inc., and The Association of Systematics Collections, Lawrence, Kansas, 732 pp.). However, documented records are known thus far from Itaguaí (ca. 22°53'S, 43°47'W) in the state of Rio de Janeiro. Specimens from the state of Espírito Santo probably represent a distinct, smaller species (J. Jim, pers. comm. and pers. obs.).

Submitted by **JOSE P. POMBAL, JR.**, Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas, Caixa Postal 6109, 13081 Campinas, São Paulo, Brazil and **ROGÉRIO P. BASTOS**, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Caixa Postal 178, 13500 Rio Claro, São Paulo, Brazil.

BUFO DEBILIS (Green Toad). USA: KANSAS: Greeley Co: Sec. 8–11, T16S, R39W. 6 July 1991. KU 218823–827; Hamilton Co: SE 1/4 Sec. 12, T26S, R42W. 6 July 1991. KU 218838–844; Wichita Co: Sec. 19, T16S, R38S, 7 July 1991. KU 218845. All collected by Travis W. Taggart & Jay Taggart. All verified by Joseph T. Collins. Helps to fill in the little known and spotty distribution of this species in western Kansas (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356).

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

BUFO MARINUS (Giant Toad). USA: FLORIDA: Pasco Co: Dade City, 700 S. 26th Street. 3 July 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 81843. New county record (D. L. Auth, Florida Mus. Nat. Hist., pers. comm.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

BUFO QUERCICUS (Oak Toad). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 34, T19S, R22E. 26 April 1991. D. Crowe

and D. Stevenson. UF 80797. Verified by D. L. Auth. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 3. The Amphibians. Windward Publ., Inc., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

GASTROPHRYNE CAROLINENSIS (Eastern Narrowmouth Toad). USA: ALABAMA: Walker Co: 1.6 km N and 1.6 km W of Pocahontas, Lost Creek at Mill Creek confluence. 3 May 1985. J. N. Stuart. Verified by William G. Degenhardt. Museum of Southwestern Biology (MSB 45206–07); ca. 1.6 km NNE of Townley, Lost Creek at Holly Grove, rain pool. 6 September 1985. J. N. Stuart. Verified by Paulette L. Ford. MSB 46323 (lot of 12 tadpoles). First records for county (Mount 1975, Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exper. Station, Auburn, Alabama, 347 pp.). Collected under Alabama Dept. Conservation Permit No. 173.

Submitted by **JAMES N. STUART**, Museum of Southwestern Biology, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

HYLA CHRYSOSCELIS (Cope's Gray Treefrog). USA: FLORIDA: Citrus Co: hydric hammock, ca. 2.1 km N Crystal River, Sec. 17, T18S, R17E. 26 April 1991. D. Crowe & D. Stevenson. UF 80799. First record for county and extends range S from nearest record in Levy Co; Sumter Co: hydric hammock near jct SR 44/CR 470, Sec 11, T19S, R21E. 9 April 1991. D. Crowe & D. Stevenson. UF 80548–49. Both verified by D. L. Auth. First record for county and extends range S from nearest record in Marion Co. (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 3. The Amphibians. Windward Publ., Inc., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

HYLA GRATIOSA (Barking Treefrog). USA: MISSISSIPPI: Lafayette Co: University of Mississippi Biological Field Station, ca. 9.6 km NE Oxford (Secs. 34 and 35, T7S, R2W; Sec. 3, T8S, R2W). 18 June 1977. W. D. Matthews. UMS 182; 10 June 1977. E. D. Keiser. UMS 219–221; 6 June 1978. D. R. Brooks. UMS 338, 352; 8 June 1978. H. L. Schuster. UMS 402; 13 August 1979. M. J. Balthazar. UMS 1490; 10 July 1979, M. J. Balthazar. UMS 1492–1495; June, July, August 1979. M. J. Balthazar. UMS 1702–1737; 1 June 1979. M. J. Balthazar. UMS 1859; 8 May 1979. M. J. Balthazar. UMS 1860; 18 June 1981. H. L. Schuster. UMS 1974; 18 June 1981. J. Goddard. UMS 1991; 9 June 1981. J. Shaw. UMS 2008; 9 June 1981. S. A. House. UMS 2019; 27 June 1984. D. Mitchell. UMS 2490; 20 June 1984. E. Dixon. UMS 2501; 12 June 1984. L. Schutz. UMS 2515; 23 June 1984. C. Davenport. UMS 2532; 20 June 1984. M. Walton. UMS 2535; 17 June 1985. E. D. Keiser. UMS 2667. Lafayette Co: ca. 1 km S Oxford, Old Taylor Road. 13 August 1979. M. J. Balthazar. UMS 1491; Marshall Co: Wall Doxey State Park. 25 May 1986. E. D Keiser. UMS 2674–2675. All 63 specimens are in the University of Mississippi collections and most were verified by Michael J. Balthazar. Lohoefener and Altig (1983, Mississippi Herpetology. Mississippi State Univ., Mississippi, 66 pp.) included *Hyla gratiosa* as a "Group Two" species in Mississippi. Group Two species were most common in southern Mississippi and had ranges generally south of an east-west line extending approximately from Meridian to Vicksburg. Map 294 of Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, 450 pp.) was based to a large extent on Lohoefener and Altig (1983) and indicated no records for the northern half of Mississippi. *Hyla gratiosa* is abundant at a number of localities in Lafayette and Marshall counties in northern Mississippi. My students and I have studied the population at the University of Mississippi Biological Field Station since 1977. In 1980, Michael J. Balthazar completed his thesis on the frogs at this site [A Comparative Study of Selected Larval States of *Hyla gratiosa* LeConte and *Hyla cinerea* (Schneider). Master's Thesis, Univ. Mississippi, Oxford, 99 pp.].

Submitted by **EDMUND D. KEISER, JR.**, Department of Biology, University of Mississippi, University, Mississippi 38677, USA.

PSEUDACRIS CRUCIFER BARTRAMIANA (Southern Spring Peeper). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 34, R22E, T19S. 10 January 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80230–32. First record for county and extends range S of nearest record in Marion Co. (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 3. The Amphibians. Windward Publ., Inc., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

PSEUDACRIS CRUCIFER CRUCIFER (Northern Spring Peeper). USA: OHIO: Butler Co: Oxford Twp., Sec 2, Hueston Woods State Park, marsh south of the Acton Lake dam. 20 March 1984. Jeffrey G. Davis & Jeffrey S. Miller. Miami University (MU A-508); Morgan township: Sec. 7, vernal pond at north end Governor Bebb Park. 21 March 1984. Jeffrey G. Davis & Jeffrey S. Miller. MU A-507. Both verified by Paul M. Daniel; Reily township: Sec. 16, vernal pond 200 m S Indian Creek Park parking lot. 28 April 1984. Jeffrey G. Davis & George Burkhart. Cincinnati Museum of Natural History (CMNH 2971). Verified by John W. Ferner. County record.

Submitted by **PAUL J. KRUSLING** and **JEFFREY G. DAVIS**, Department of Herpetology, Cincinnati Museum of Natural History, Frederick and Amey Geier Research and Collections Center, 1720 Gilbert Avenue, Cincinnati, Ohio 45202, USA.

PSEUDACRIS NIGRITA VERRUCOSA (Florida Chorus Frog). USA: FLORIDA: Pinellas Co: SE 1/4 Sec. 24, T27S, R16E, 9.4 km (airline) N Oldsmar. 4 April 1991. James C. Godwin. Verified by David Auth. UF 81725. Single late chorusing male collected from a flooded rut near a disturbed marsh. New county record; extends range westward from Hillsborough Co. (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 3. The Amphibians. Windward Publ., Inc., Miami, 191 pp.).

Submitted by **JAMES C. GODWIN**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

PSEUDACRIS OCULARIS (Little Grass Frog). USA: FLORIDA: Citrus Co: St. Martin's Aquatic Preserve, Sec. 32, T18S, R17E. 28 January 1991. D. Crowe & D. Stevenson. UF 80561; Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 34, T19S, R22E. 19 March 1991. D. Crowe & D. Stevenson. UF 80563. Both verified by D. L. Auth. New county records (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 3. The Amphibians. Windward

Publ., Inc., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

PSEUDACRIS OCULARIS (Little Grass Frog) USA: FLORIDA: Pinellas Co: SE 1/4 Sec. 24, T27S, R16E, 9.4 km (airline) N Oldsmar. 4 April 1991. James C. Godwin. Verified by David Auth. UF 81723. One male collected from a flooded disturbed marsh. Numerous individuals were present at this locality and in the vicinity. New county record; extends range westward from Hillsborough Co. (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 3. The Amphibians. Windward Publ., Inc., Miami, 191 pp.).

Submitted by **JAMES C. GODWIN**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

RANA AREOLATA CIRCULOSA (Northern Crawfish Frog). USA: ARKANSAS: Jackson Co: 9 km NW Possum Grape, Sec. 5, T10N, R4W. 13 March 1989. Jonathan D. White & Thomas W. Duncan. Arkansas State University Museum of Zoology (ASUMZ 14298); Faulkner Co: 0.4 km W Enola on Ark. Rt. 310, Sec. 32, T7N, R11W. 18 February 1992. Jonathan D. White, Cheryl K. White & Hamilton N. Holliman. ASUMZ 18412. Both verified by Stanley E. Trauth. County record extending known range ca. 40 km NE and county record within known range, respectively (Plummer 1977, Herpetol. Rev. 8:38; Turnipseed 1990, Herpetol. Rev. 21:21–22).

Submitted by **MICHAEL V. PLUMMER** and **JONATHAN D. WHITE**, Department of Biology, Harding University, Searcy, Arkansas 72143, USA.

RANA CATESBEIANA (Bullfrog). USA: FLORIDA: Sumter Co: CR 470, 4.1 km NW Lake Panasoffkee, Sec. 25, R21E, T19S. 10 January 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80242. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 3. The Amphibians. Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

RANA GRYLIO (Pig Frog). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 34, T19S, R22E. 9 April 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80554. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 3. The Amphibians. Windward Publ., Inc., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). USA: FLORIDA: Sumter Co: CR 470, 4.1 km NW Lake Panasoffkee, Sec. 25, T19S, R21E. 10 January 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80227. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 3. The Amphibians. Windward Publ., Inc., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

CROCODYLIA

ALLIGATOR MISSISSIPPIENSIS (American Alligator). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 12, T20S, R22E. 14 March 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80808. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians., Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

TESTUDINES

APALONE MUTICA (Smooth Softshell). USA: OHIO: Hamilton Co: Columbia Twp., Little Miami River, Kroger Hill Park, 0.5 km downstream from mouth of E Fork Little Miami River. 23 June 1991. Paul J. Krusling & Wayne R. Wauligman. Cincinnati Museum of Natural History (CMNH 3393); Miami Twp., Great Miami River, 50 m N of the Shawnee Lookout Park Boat Ramp. 12 June 1988. Paul J. Krusling & M. Suzanne Simon. CMNH 2901. Both verified by John W. Ferner. New county records and first records for each river system.

Submitted by **PAUL J. KRUSLING** and **JEFFREY G. DAVIS**, Department of Herpetology, Cincinnati Museum of Natural History, Frederick and Amey Geier Research and Collections Center, 1720 Gilbert Avenue, Cincinnati, Ohio 45202, USA.

APALONE SPINIFERA HARTWEGI (Western Spiny Softshell). USA: NEBRASKA: Cherry Co: Mill Pond on Minnechaduza Creek, 0.8 km NW center of Valentine, SW 1/4 Sec. 30, T34N, R27W, 757 m elev. 18 August 1991. N. J. Scott, Jr. & J. N. Stuart. Verified by Paul Stephen Corn. U. S. Biological Survey Collection, Fort Collins, Colorado (BS/FS 6556). First record for the county and the Niobrara River basin (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **JAMES N. STUART** and **NORMAN J. SCOTT, JR.**, National Ecology Research Center, U. S. Fish and Wildlife Service, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

CARETTA CARETTA (Loggerhead). USA: ALASKA: Shuyak Island, Carry Inlet (58.33°N, 152.32°W). 31 December 1991. Headless female carcass on beach at high tide line. Carapace SL length 725 mm, carapace SL width 613 mm, weight 37.8 kg. Verified by Gil Bane & Ken Hansen. National Marine Fisheries Service Collection (Kodiak College GWB 970301, Kodiak, Alaska). Gulf of Alaska specimen is the first Alaskan *Caretta* and the northernmost eastern Pacific Ocean record to date (Hodge 1982, Herpetol. Rev. 13:24).

Submitted by **ROBERT PARKER HODGE**, 181 Raft Island, Gig Harbor, Washington 98335, USA.

CHELYDRA SERPENTINA OSCEOLA (Florida Snapping Turtle). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 10, T20S, R22E. 16 March 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80804. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards,

Turtles and Crocodilians., Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

DEIROCHELYS RETICULARIA MIARIA (Western Chicken Turtle) USA: TEXAS: Montgomery Co: 8.5 km SE of Todd Mission on FM 1774. 20 April 1991. Troy D. Hibbitts. Verified by James R. Dixon. Texas Cooperative Wildlife Collection (TCWC 68350). New county record. (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station, Texas, 434 pp.).

Submitted by **TROY D. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77840, USA.

GRAPTEMYS PSEUDOGEOGRAPHICA (False Map Turtle). USA: KANSAS: Mitchell Co: Oak Creek at Glen Elder Reservoir, 1.2 km E Osborne County line, Sec. 17, T6S, R10W. 18 May 1991. Travis W. Taggart. Verified by Joseph T. Collins. KU 218898. Extends the range 213 km WNW from the previously most northwestern Kansas record in Morris Co. and represents the most western record in the Kansas River system (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356; Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston, 450 pp.).

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

KINOSTERNON FLAVESCENS (Yellow Mud Turtle). USA: KANSAS: Labette Co: 2.1 km NW Chetopa on U.S. Rt. 166. 4 June 1989. Travis W. Taggart. Verified by Joseph T. Collins. KU 211400. Substantiates the presence of an isolated colony in southeastern Kansas and adjacent states (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356; Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston, 450 pp.).

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

KINOSTERNON SUBRUBRUM STEINDACHNERI (Florida Mud Turtle). USA: FLORIDA: Sumter Co: CR 470, 3.7 km NW Lake Panasoffkee, Sec. 25, T19S, R21E. 23 April 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80807. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians., Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

MACROCLEMYS TEMMINCKII (Alligator Snapping Turtle). USA: INDIANA: Morgan Co: adult female taken on floodplain of Westfork, White River, 2 km NNW Martinsville. ca. 3 March 1991. David Ferran. Verified by C. J. McCoy. CM Acc. No. 35067. County record and first for Indiana in many years, where it had been considered extirpated (Minton 1972, Amphibians and Reptiles of Indiana. Indiana Acad. Sci. Monogr. 3:1-346; Swanson 1939, Amer. Midl. Nat. 22:684-695)

Submitted by Michael J. Lodato, 925 Park Plaza Drive, Evansville, Indiana 47715, USA, **LOUIS T. GRANNAN, JR.**, 921 West Iowa Street, Evansville, Indiana 47710, USA, and **ROBERT ANDERSON**, Indiana Department of Natural Resources, Division of Fish and Wildlife, 402 West Washington Street, Indianapolis, Indiana 46204, USA.

PSEUDEMYS CONCINNA METTERI (Missouri River Cooter) USA: TEXAS: Leon Co: 0.8 km W of Buffalo on US Rt. 79. 12 May 1991. Troy D. Hibbitts. Verified by James R. Dixon. Texas Cooperative Wildlife Collection (TCWC 67317). New county record along the western edge of this subspecies distribution in Texas. (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station, Texas, 434 pp.).

Submitted by **TROY D. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77840, USA.

PSEUDEMYS NELSONI (Florida Redbelly Turtle). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 10, T20S, R22E. 4 April 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 83468 (photograph). New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians., Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

STERNOTHERUS MINOR MINOR (Loggerhead Musk Turtle). USA: FLORIDA: Sumter Co: Little Jones Creek, Sec. 17, T19S, R22E. 1 August 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 81851–52. First record for Sumter Co. and extends range ca. 21 km W of nearest record in Lake Co. (Iverson and Etcheberger 1989, Florida Scientist 52(2):104–118).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

STERNOTHERUS ODORATUS (Common Musk Turtle). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 10, T20S, R22E. 1 January 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80187. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians., Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider) USA: INDIANA: Dearborn Co: Lawrenceburg Twp: Sec. 1, 0.5 km W Ohio border and 1.1 km N Kentucky border. 1 May 1988. Paul J. Krusling & Wayne R. Wauligman. Verified by John W. Ferner. Cincinnati Museum of Natural History (CMNH 2902). New county record (Minton 1972, Amphibians and Reptiles of Indiana. Indiana Acad. Sci. Monogr. 3:1-346).

Submitted by **PAUL J. KRUSLING** and **JEFFREY G. DAVIS**, Department of Herpetology, Cincinnati Museum of Natural History, Frederick and Amey Geier Research and Collections Center, 1720 Gilbert Avenue, Cincinnati, Ohio 45202, USA.

AMPHISBAENIA

AMPHISBAENA ALBA (Worm Lizard). BRAZIL: RIO DE JANEIRO: Maricá Co: Restinga da Barra de Maricá (22° 57' S, 43° 50' W). On the sand beach habitat of the Restinga 50 m from the sea. 13 August 1986. Female 315 + 27.7 mm. C. F. D. Rocha & R. F. Fialho. Verified by Ulisses Caramaschi. Museu Nacional do Rio de Janeiro, Universidade Federal do Rio de Janeiro (MNRJ 4298). First documented record for Rio de Janeiro State, extends the range to Rio de Janeiro. This amphisbaenian has large distribution over South America from Venezuela, Guyanas, Colombia, Peru and Bolivia east of Andes, throughout Brazil to northern Paraguay (Peters and Donoso-Barros 1970, Bull. U. S. Nat. Mus. 297:29). In Brazil this species has been reported from many habitats (morphoclimatic domains, sensu Ab´Saber 1967, Dept. Geogr. Fac. Cienc. Latr. Univ. S. Paulo 3:45–48) including forested lowlands of Amazonia, savannas of central Brazil (locally called cerrado), Atlantic forest, Pantanal of Mato Grosso and Northeastern caatingas [Vanzolini 1955, Arq. Mus. Nac. Rio de Janeiro 42:683–706; 1968. Pap. Avuls. Zool. São Paulo 21(23):231–241]. However, this is the first record of this species in the coastal sand dune habitats (called restinga). Vanzolini (1968, op. cit.) showed a significant cline in the number of body annuli of *A. alba* latitudinally related to environmental temperature. He was not able to show the pattern of body annuli of this species in the State of Rio de Janeiro due to the lack of specimens from the area. The number of body annuli in our specimen (215 + 16) is similar to that recorded to adjacent areas of southeastern Brazil (Vanzolini 1955, op. cit.; 1968, op. cit.) and is consistent with that predicted by Vanzolini (1968, op. cit.) at the latitude of Rio de Janeiro.

Submitted by **CARLOS FREDERICO DUARTE ROCHA**, Setor de Ecologia, Departamento de Biologia Animal e Vegetal, Instituto de Biologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, Maracanã 20550, Rio de Janeiro, Brazil.

LACERTILIA

ANOLIS CAROLINENSIS (Green Anole). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 10, T20S, R22E. 1 January 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80219. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians, Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

ANOLIS SAGREI (Brown Anole). USA: FLORIDA: Citrus Co: St. Martin's Aquatic Preserve, Sec. 32, T18S, R17E. 17 June 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 81850. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians, Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 20, T20S, R22E. 26 March 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80540. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians, Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

EUMECES EGREGIUS ONOCREPIS (Peninsula Mole Skink). USA: FLORIDA: Hillsborough Co: SE 1/4 Sec. 25, T28S, R20E, 12.6 air km W Plant City. 22 February 1991. James C. Godwin. Verified by David Auth. UF 81699. Collected from an ecotonal zone between upland forest and mesic flatwoods. County record and fills gap between Pinellas and Polk counties (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians, Windward Publ., Miami, 191 pp.).

Submitted by **JAMES C. GODWIN**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

EUMECES LATICEPS (Broadhead Skink). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 34, T19S, R22E. 26 March 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80529–30. County record and fills gap between Lake and Citrus counties (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians, Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

EUMECES OBSOLETUS (Great Plains Skink). USA: KANSAS: Rawlins Co: Section 21, T1S, R33W. 19 August 1990. Travis W. Taggart. Verified by Joseph T. Collins. KU 217220. Helps fill hiatus between adjacent records in northeastern Colorado and southwestern Nebraska (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356; Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver, 131 pp.; Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

EUMECES OBTUSIROSTRIS (Southern Prairie Skink). USA: MISSOURI: Barton Co: Prairie State Park. 10 April 1992. Kevin R. Toal & Randall S. Reiserer. Verified by Joseph T. Collins. KU 219997. First record for the state; extends the range of this species ca. 90 km NW of nearest known locality in Oklahoma (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston, 450 pp.).

Submitted by **KEVIN R. TOAL** and **RANDALL S. REISERER**, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045, USA.

EUMECES SEPTENTRIONALIS (Prairie Skink). USA: NEBRASKA: Saunders Co: Sec. 23, T15N, R9E. 7 May 1989. J. Mathew Weekly. Verified by John D. Lynch. University of Nebraska State Museum (UNSM 9829). New county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **J. MATHEW WEEKLY**, Department of

Otolaryngology and Head and Neck Surgery, University of Nebraska Medical Center, Omaha, Nebraska 68198, USA, and **JODY L. HAYNES**, Department of Biological Sciences, University of New Orleans, New Orleans, Louisiana 70148, USA.

HEMIDACTYLUS GARNOTI (Indo-Pacific Gecko). USA: FLORIDA: Citrus Co: 5.2 km E Inverness, Sec. 10, T19S, R20E. Adult specimen collected at campground. 9 May 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80802. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians, Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

MABUYA DORSIVITTATA (NCN). ARGENTINA: BUENOS AIRES: Municipio Urbano de la Costa: Costa Azul (36°40'S 56°40'30"W). 15 November 1989. P. J. Bellagamba & L. E. Vega. Verified by Jorge Williams. Herpetological Collection of the Vertebrate Laboratory, Departmento de Biologia, Universidad Nacional de Mar del Plata (UNMdP-0166). First record for the county (Cei 1986, Mus. Reg. Sci. Nat. Torino Monogr. 4:1–527). Adult captured in coastal sand dunes with grass cover. A doubtful record without collection data exists for the city of Mar del Plata (Liebermann 1939, Physis 16:61–82). Until this can be corroborated, the present record extends the range of this lizard 150 km SE from nearest known locality in Partido de Magdalena, and is the first for the Atlantic Coast (Williams 1991, Situacion ambiental de la provincia de Buenos Aires. A-Recursos y rasgos naturales en la evaluacion ambiental. Anfibios y reptiles. CIC. Ano I No. 4. 21 pp.).

Submitted by **LAURA E. VEGA** and **PATRICIO BELLAGAMBA**, Lab. Vertebrados, Departamento de Biologia, Universidad Nacional de Mar del Plata, Funes 3350, 7600 Mar del Plata, Argentina.

NEOSEPS REYNOLDSI (Sand Skink). USA: FLORIDA: Orange Co: 3.1 km E jct CR 545/SR 192, Sec. 33, T24S, R27E. 24 February 1990. D. Stevenson. Verified by D. L. Auth. UF 80185. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians, Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

OPHISAURUS COMPRESSUS (Island Glass Lizard). USA: FLORIDA: Glades Co: 1 km E jct CR# 731/SR# 74. 1 March 1991. K. Enge & B. Kellnerr. Verified by D. L. Auth. UF 80543–44. Collection site bordered by xeric flatwoods/palmetto prairie habitat. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians, Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

OPHISAURUS VENTRALIS (Eastern Glass Lizard). USA: FLORIDA: Sumter Co: 1.8 km N Carlson on CR 470, Sec. 14, T19S, R21E. 4 June 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 81847. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians, Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

SCINCELLA LATERALIS (Ground Skink). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 34, T19S, R22E. 29 March 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 80537. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians, Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

SERPENTES

CLONOPHIS KIRTLANDII (Kirtland's Snake) USA: OHIO: Butler Co: Fairfield Twp., Sec. 22, Gilmore Ponds, at jct. Symmes Road and Berk Boulevard. 25 October 1991. James Becker & Jeffrey G. Davis. Verified by John W. Ferner. Cincinnati Museum of Natural History (CMNH 3459). First county record and verifies 50-year old report (Fichter 1947, Herpetologica 4:71–73).

Submitted by **PAUL J. KRUSLING** and **JEFFREY G. DAVIS**, Department of Herpetology, Cincinnati Museum of Natural History, Frederick and Amey Geier Research and Collections Center, 1720 Gilbert Avenue, Cincinnati, Ohio 45202, USA.

COLUBER CONSTRICTOR (Racer). USA: NEBRASKA: Garfield Co: 12.8 km N and 3.2 km E of Burwell. 11 September 1958. C. J. Jones. Verified by William G. Degenhardt. Museum of Southwestern Biology (MSB 4743). New county record; partially fills hiatus in central part of state (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **JAMES N. STUART**, Museum of Southwestern Biology, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellowbelly Racer) USA: COLORADO: Elbert Co: 1.2 km E & 6.5 km N of Agate (NW 1/4, Sec. 20, T6S, R58W). 31 August 1991. David Chiszar & David Drew. Verified by Jeffrey B. Mitton. University of Colorado Museum of Natural History (UCM 56509). New county record (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Department of Natural Resources, Denver, 131 pp.).

Submitted by **DAVID CHISZAR**, Department of Psychology and Museum of Natural History, University of Colorado, Boulder, Colorado 80309 USA, **J. DAVID DREW**, Campion Academy, SW 42nd and Academy Drive, Loveland, Colorado 80537 USA, and **HOBART M. SMITH**, Department of EPO Biology and Museum of Natural History, University of Colorado, Boulder, Colorado 80309, USA.

COLUBER CONSTRICTOR MORMON (Western Yellowbelly Racer). USA: COLORADO: Moffat Co: 35.4 km SW Craig (SW 1/4 Sec. 21, T4N, R93W). 25 July 1991. Jan J. Roth. Verified by Hobart M. Smith. University of Colorado Museum of Natural History (UCM 56512). First county record, although there is an earlier record of this species 113 km NW at the border of Moffat Co., Colorado, and Uintah Co., Utah (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Depart-

ment of Natural Resources, Denver, 131 pp.).

Submitted by **JAN J. ROTH,** Sundance Museum, Craig, Colorado 81625, USA, and **DAVID CHISZAR**, Department of Psychology and Museum of Natural History, University of Colorado, Boulder, Colorado 80309, USA.

CROTALUS HORRIDUS (Timber Rattlesnake). USA: VIRGINIA: Prince William Co: Prince William Forest Park, 5.5 km WNW Triangle. 15 September 1991. Marie Frias. USNM 314213 (DOR neonate); 19 October 1991. Tom Davis. USNM 314211 (DOR adult). Both verified by Roy W. McDiarmid. New county records and only records near the Fall line in the Virginia Piedmont; extend the range 40 km SE of nearest extant record in Bull Run Mountains (Fauquier Co.), and ca. 170 km NNW of nearest Coastal Plain records in southeastern (York Co.) Virginia (Tobey 1985, Virginia's Amphibians and Reptiles, a Distributional Survey. Publ. Virginia Herpetol. Soc., Purcellville, Virginia. 114 pp.).

Submitted by **WILLIAM H. MARTIN,** Route 3, Box 804, Harper's Ferry, West Virginia 25425, USA, **JOSEPH C. MITCHELL**, Department of Biology, University of Richmond, Richmond, Virginia 23173, USA, and **RILEY HOGGARD**, Prince William Forest Park, P. O. Box 209, Triangle, Virginia 22172, USA.

CROTALUS VIRIDIS (Western Rattlesnake). USA: KANSAS: Jewell Co: Sec. 19, T2S, R8W. 27 July 1991. Travis W. Taggart. Verified by Joseph T. Collins. KU 218889–890. Substantiates a questionable record from Republic Co. to the east (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356).

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

DIADOPHIS PUNCTATUS ARNYI (Prairie Ringneck Snake) USA: TEXAS: Edwards Co: 9.1 km NE of Rocksprings on US Rt. 377. 10 August 1991 Troy D. Hibbitts. Verified by James R. Dixon. Texas Cooperative Wildlife Collection (TCWC 69200). New county record; fills distributional hiatus between the range of this subspecies and the western form *D. p. regalis* in southwest Texas, with *D. p. regalis* occurring to the west in the adjacent Val Verde Co. and *D. p. arnyi* occurring to the east in the adjacent Real Co. (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station, Texas, 434 pp.). Adult male measuring 253 mm SVL/64 mm tail, exhibits color, pattern, and scutellation typical of D. *p. arnyi*, as per Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston, 450 pp.).

Submitted by **TROY D. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77840, USA.

ELAPHE OBSOLETA (Rat Snake). USA: NEBRASKA: Jefferson Co: Sec. 15, T1N, R3E. 3 May 1989. Jody L. Haynes. Verified by John D. Lynch. University of Nebraska State Museum (UNSM 9833). New county record; fills a gap in known distribution in Nebraska (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **J. MATHEW WEEKLY,** Department of Otolaryngology and Head and Neck Surgery, University of Nebraska Medical Center, Omaha, Nebraska 68198, USA, and **JODY L. HAYNES**, Department of Biological Sciences, University of New Orleans, New Orleans, Louisiana 70148, USA.

FARANCIA ABACURA (Mud Snake). USA: ARKANSAS: Pope Co: SW 1/4 NE 1/4 Sec 31, T8N, R20W. 2 April 1991. Glyn Turnipseed. Verified by Matt Gallagher. KU 220059. County record and northwestward range extension in the state (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, 450 pp.)

Submitted by **GLYN TURNIPSEED**, Department of Biology, Arkansas Tech University, Russellville, Arkansas 72801, USA.

HETERODON PLATIRHINOS (Eastern Hognose Snake). USA: KANSAS: Graham Co: ca. 23.2 km S and 16.3 km E Hill City. 3 September 1989. KU 212558; Norton Co: Sec. 26, T4S, R21W. 19 September 1990. KU 217229; Gove Co: Sec. 12, T15S, R42W. 17 June 1990. KU 216129. All collected by Travis W. Taggart. Verified by Joseph T. Collins. These are the most northwestern records for this species in the state (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356).

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

HETERODON SIMUS (Southern Hognose Snake). USA: FLORIDA: Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), R22E, T20S, Sec 10. 15 May 1991; sandhill adjacent to SR 44, 4.6 km E jct SR 44/CR 470, Sec. 6, T19S, R22E. 25 October 1991. D. Crowe & D. Stevenson. UF 80772 & 83443. Both verified by D. L. Auth. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second ed. Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

LAMPROPELTIS GETULA (Common Kingsnake). USA: KANSAS: Hamilton Co: below Hamilton County State Lake, Sec. 28, T23S, R41W. 7 July1991. Travis W. Taggart. Verified by Joseph T. Collins. KU 218867. Helps to substantiate the population of this serpent along the Arkansas River in both Kansas and Colorado (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356; Hammerson 1986, Amphibians and Reptiles in Colorado. Second Printing. Colorado Division of Wildlife, Denver, 131 pp.).

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

NERODIA SIPEDON (Northern Water Snake). USA: KANSAS: Cheyenne Co: Sec. 10, T1S, R42W. 21 July 1990. Travis W. Taggart. Verified by Joseph T. Collins. KU 217230. Confirms its existence in extreme northwestern Kansas and helps to fill hiatus between adjacent records in northeastern Colorado and southwestern Nebraska (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356; Hammerson 1986, Amphibians and Reptiles in Colorado. Second Printing. Colorado Division of Wildlife, Denver, 131 pp.; Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

OPHEODRYS AESTIVUS (Rough Green Snake). USA: FLORIDA: Sumter Co: CR 470, 3.7 km NW Lake Panasoffkee, Sec. 25, T19S, R21E. 1 August 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 81831. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes.

Second ed. Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811 USA.

OPHEODRYS AESTIVUS (Rough Green Snake) USA: TEXAS: Lavaca Co: 9.9 km N of jct FM 682 on US Rt. 77. 25 April 1991. Troy D. Hibbitts. Verified by James R. Dixon. Texas Cooperative Wildlife Collection (TCWC 68333). New county record (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station, Texas. 434 pp.).

Submitted by **TROY D. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77840, USA.

PITUOPHIS MELANOLEUCUS MUGITUS (Florida Pine Snake). USA: FLORIDA: Sumter Co: Sec. 6, T19S, R22E, sandhill adjacent to SR 44, 4.6 km E jct SR 44/CR 470. 18 September 1991. D. Crowe & D. Stevenson. Verified by D. L. Auth. UF 83633 (photograph, adult male). County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second ed. Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

RHADINAEA FLAVILATA (Pine Woods Snake). USA: FLORIDA: Bay Co: 4.5 air km SSW Ebro (Sec. 18, T1S, R16W). 19 September 1991. John G. Palis. Verified by David L. Auth. UF 84079. New county record; second collection from the Florida panhandle W of Apalachicola River (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second ed. Windward Publ., Miami, Florida, 191 pp.).

Submitted by **JOHN G. PALIS**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA.

RHADINAEA FLAVILATA (Pine Woods Snake). USA: FLORIDA: Pinellas Co: SE 1/4 Sec. 13, T27S, R16E, 10.7 air km N of Oldsmar. 8 May 1991. James C. Godwin. Verified by David Auth. UF 81633. Collected within a hydric hardwood hammock. County record; extends range westward from Hillsborough Co. (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second ed. Windward Publ., Miami, 191 pp.).

Submitted by **JAMES C. GODWIN**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

STORERIA DEKAYI (Brown Snake). USA: KANSAS: Sheridan Co: Sheridan County State Lake. 6 June 1992. Kevin R. Toal & Lori McElroy. Verified by Joseph T. Collins. KU 219998. New county record; extends range ca. 60 km W (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, 450 pp.) and verifies the record from Graham Co. reported by Collins (1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356).

Submitted by **KEVIN R. TOAL**, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045, USA.

STORERIA DEKAYI (Brown Snake). USA: NEBRASKA: Saunders Co: Sec. 23, T15N, R9E. August 1989. J. Mathew Weekly. Verified by John D. Lynch. University of Nebraska State Museum (UNSM 9836). New county record; extends range ca. 25 km N in Nebraska (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **J. MATHEW WEEKLY**, Department of Otolaryngology and Head and Neck Surgery, University of Nebraska Medical Center, Omaha, Nebraska 68198, USA, and **JODY L. HAYNES**, Department of Biological Sciences, University of New Orleans, New Orleans, Louisiana 70148, USA.

STORERIA DEKAYI VICTA (Florida Brown Snake). USA: FLORIDA: Sumter Co: CR 470, 3.7 km NW Lake Panasoffkee, Sec. 25, T19S, R21E. 9 April 1991. Collector unknown. Verified by D. L. Auth. UF 80512. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second ed. Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

STORERIA OCCIPITOMACULATA (Redbelly Snake). USA: FLORIDA: Pasco Co: S Hudson, SR 52, 8 km E jct US Rt. 19. 1983. Collector unknown. Verified by P. E. Moler. USNM 245390. County record; extends range south of nearest record in Citrus Co.; Sumter Co: Southwest Florida Water Management District (SWFMD) Property (Berry Tract), Sec. 34, T19S, R22E. 9 April 1991. D. Crowe and D. Stevenson. UF 80511. Verified by D. L. Auth. County record; extends range south from nearest record in Marion Co. (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second ed. Windward Publ., Miami, 191 pp.).

Submitted by **DIRK STEVENSON** and **DAVID CROWE**, Florida Game and Fresh Water Fish Commission, 3900 Drane Field Road, Lakeland, Florida 33811, USA.

THAMNOPHIS SIRTALIS (Common Garter Snake). USA: KANSAS: Rawlins Co: South Fork Driftwood Creek, 14.5 km N and 1.6 km E Atwood, Sec. 28, T1S, R33W. 19 August 1990. KU 217234; Norton Co: Sec. 20, T3S, R23W. 18 May 1991. KU 218886. Both collected by Travis W. Taggart. Both verified by Joseph T. Collins. Extends range into northwestern Kansas and helps to fill hiatus between adjacent records in northeastern Colorado and southwestern Nebraska (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356; Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver, 131 pp.; Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

TYPHLOPS MICROSTOMUS (NCN). BELIZE: COROZAL DISTRICT: Sarteneja. 27 June 1991. J. C. Meerman. Verified by M. S. Hoogmoed. National Naturhistorisch Museum, Leiden (RMNH 25946). Previously known from the Peten region of Guatemala (Campbell and Vannini 1989, Proc. W. Found. Vert. Zool. 4:1–21), this is the first record of this species for Belize. Found at depth of 1.6 m in a well being excavated, although it may have fallen into the pit.

Submitted by **J. C. MEERMAN**, P. O. Box 134, Orange Walk, Belize.

VIRGINIA STRIATULA (Rough Earth Snake) USA: TEXAS: Madison Co: 14.2 km N of Iola on FM 39. 11 May 1991. Troy D Hibbitts. Verified by James R. Dixon. Texas Cooperative Wildlife Collection (TCWC 68334). New county record (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press,

College Station, Texas, 434 pp.).

Submitted by **TROY D. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77840, USA.

VIRGINIA VALERIAE ELEGANS (Western Earth Snake). USA: MISSOURI: Adair Co: Rt. 157 at the entrance to Thousand Hills State Park, Sec. 1, T62N, R16W (DOR). 2 May 1992. Robert Powell. Verified by J. S. Parmerlee, Jr. Bobby Witcher Memorial Collection (BWMC 04801), Avila College. New county record within a hiatus in the range indicated by Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, 450 pp.). Johnson (1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Cons., Jefferson City, 368 pp.) speculated that this species was present in northeastern Missouri (presumably based on records in southern Iowa, western Illinois, and central Missouri), but included no records backed by voucher specimens.

Submitted by **ROBERT POWELL**, Department of Natural Sciences, Avila College, Kansas City, Missouri 64145, USA.

BOOK REVIEWS

Checklist of the Amphibians and Reptiles of Connecticut with Notes on Uncommon Species, by Michael W. Klemens. 1991. Connecticut Department of Environmental Protection Bulletin No. 14. Natural Resource Center, Publications Sales, Rm. 555, 165 Capitol Avenue, Hartford, Connecticut 06106, USA. (24 pp. with 50 color photographs). $6.00 for 1 copy, $4.20 for 3-10 copies and $3.65 for 11 copies or more.

Very little has been published on the herpetofauna of the New England region, due mostly to the less diverse nature of the fauna compared to the rest of the contiguous United States. This is not to say that the area's fauna is of no interest or that it has not been studied. Most recent publications have dealt with the region as a whole and have not concentrated on any one state. This checklist is a welcome addition to the literature.

The author's purpose is to provide a brief introduction to the herpetofauna of Connecticut based on what he considers documented reports and his own fifteen years of field work. The checklist achieves this goal effectively.

In his introduction, Klemens explains his approach and summarizes the composition of Connecticut herpetofauna ("45 species, . . . twelve salamanders, ten frogs, eight turtles, one lizard and fourteen snakes. . ." p. 6) and comments generally on amphibian and reptile density throughout the state. A discussion of methods follows in which the author defines which taxa he considers "uncommon" and noteworthy for the amateur naturalist as well as for the professional. The balance of the bulletin is broken down into three sections: 1) a discussion of the species the author considers "uncommon" with general comments on their habitat, distribution, and possible reasons for their apparent rarity, 2) color photographs of all the amphibians and reptiles in Connecticut, and 3) a final checklist of Connecticut's herpetofauna that includes a summary coding of their distribution throughout the state. Included in this final list are species that have been erroneously reported as indigenous to Connecticut. These are also briefly explained in the text. Finally, a literature cited section allows the reader to locate additional, more detailed information.

The checklist itself is practical and its content, given its generality, is accurate and useful. The photographs are good to excellent, with enough detail to make the identification of adult animals relatively easy. A photograph for every Connecticut species is included. Obviously, it will still be difficult to identify amphibian larvae and juveniles as well as some of the ambystomatid salamanders, but no claim of completeness is made by the author. This bulletin is a useful addition to any library, amateur or professional, and for those interested in the herpetofauna of the New England region and Connecticut in particular, it is an especially welcome contribution.

Bibliographie Herpetologischer Bibliographien II. Amphibia, Reptilia, by Helga Braßeler. 1991. Courier Forschungsinstitut Senckenberg 140. 129 pp. Paper. DM 30, approx. US $19.20.

Compiling a bibliography is generally a thankless task; the end result is frequently used but rarely acknowledged. As a tertiary reference, the *Bibliographie der Herpetologischer Bibliographien* will almost never be cited directly, yet its potential as a research tool is significant. This volume is the second in a series of herpetological bibliographies from the Informationszentrum für Biologie at the Forschungsinstitut Senckenberg and joins several similar publications devoted to birds, bats, whales and bryophytes. The first of the herpetological bibliographies (Braßeler 1989) focused on the fields of ecology, systematics and zoogeography, and a third installment, promised for late 1992, will emphasize paleoherpetology and evolutionary biology. The present volume records 906 titles, dealing largely, but not exclusively, with physiology, genetics, biochemistry, and venoms. The criterion for inclusion in the work is that each publication cited itself has a bibliography or literature cited section of more than 100 entries. As such, the bibliography serves as a source book for comprehensive literature reviews in a variety of herpetological subdisciplines. In addition to books and journal articles, a large number of North American and European theses and dissertations are included, providing access to these difficult to trace works. The bibliography is indexed by author and by subject. The latter index is in English, with German equivalents provided only for place names that differ significantly between the two languages.

All bibliographies are incomplete to some extent, but I note that the majority of recent titles that I have used myself and that meet the criterion for inclusion have been referenced by Braßeler. The subject indexing of the bibliography, however, leaves something to be desired, and the criteria for key word choice appear to be inconsistently applied. For example, comparable systematic works dealing with suprageneric levels of hierarchy are indexed variously by the names of the genera involved, the higher order group name only, or under the group name and under "phylogeny." While many entries can undoubtedly be retrieved from the index, it would appear that maximal utility of the bibliography is achievable only by scanning all 900 entries for one's topic of interest. Nonetheless, for those whose research necessitates extensive bibliographic work, this publication will serve as a valuable aid for

locating papers in a variety of fields. It will also be useful for advanced students or others entering into new areas or wishing to explore the literature in unfamiliar branches of herpetology.

A Social History of the American Alligator. The Earth Trembles with His Thunder. by Vaughn Glasgow. St. Martin's Press, New York. vi + 260 pp., ill., cloth, $29.95.

This is a curious and fascinating book. It deals with alligators and men, but hardly from the viewpoint of most of our readership. Also the extensive bibliography does not overlap the various technical accounts recently made available. Instead we have here accounts of interactions, but mainly as reported in the popular press. Chapters deal with such topics as legends, symbolism, the history of discovery, the use of the animals and their parts, their utilization as food and some recipes, the animals in literature, films and songs and the history of hunting, protection and managed utilization. Crocodiles (and caimans) are often mentioned, but mainly as being different from alligators.

The author is director for special projects at the Louisiana State Museum and apparently there has available a remarkable collection of newspaper clippings, popular books and articles, and illustrations many of which are here excerpted or reproduced. As the book apparently derived from an exhibition, it reflects astonishing research projects involving many individuals whose efforts are detailed in a four page account.

The style of presentation is that recommended by newspaper editors, rather than in classes of scientific writing. The topic is introduced and then circumscribed, with factual and imaginary comments cited thereafter in fine abandon. In the last third or so, the author returns to the topics noted in the introductory section. For each subtopic there is the citation "in quotes" of multiple individuals (often from quotations in previous accounts, rather than personal confirmation) and some snippets of text. Apparently true and obviously misleading comments appear in parallel. The method of presentation leads to much redundancy with similar comments appearing repeatedly in successive chapters. One wonders whether the chapters were initially intended for independent publication. Clearly, the book is intended to be read through and put down, rather than used as a reference to the topic. However, the index and literature cited are good and permit one to find materials pertinent to specific issues.

One of the obvious aims of the book is to explain and defend the Louisiana pattern of controlled alligator hunting and ranching. There is an extensive discussion of the changing climate of opinion, the shift of legislation and the conflict between those aiming for conservation and absolute protection. The folk lore of the hunting community is characterized in an interesting fashion. Curiously, the Audubon Society is placed into a demonic role and the animal rights lobby is hardly mentioned. The book is full of odd snippets of fascinating information; thus, I was amazed to discover that New Orleans district attorney Jim Garrison once had given the order not to pursue a strong case against a skin poacher.

An important component is that the author acknowledges the significant contributions of scientists working on these animals, from Coulson to Joannen. Those studies that later facilitated ranching, that elicited data on sex determination and accelerated growth rate, are obviously emphasized. Ecology of the animals is hardly touched upon and the book lacks a real account of alligator biology. Hence, it had best be read in parallel with one of the several more zoologically inclined accounts that have recently appeared. The emphasis is not surprising as the animals provide the basis of a substantial industry and one that involves an area that has incurred economic depression.

In reviewing my impressions, not so much of the book, but of the events it characterizes, I am left in a quandary. Enthusiasm for controlled alligator hunting is reflected in the conservation of wetlands and the other wildlife there native. However, the hunting methods described are rather cruel. Shift to ranching could alleviate this; however, it would reduce the strength of the argument for wetlands. Protection must remain for ecological associations, rather than for particular species.

CARL GANS

Neotropical Wildlife Use and Conservation, edited by John G. Robinson and Kent H. Redford, 1991. University of Chicago Press, 5801 Ellis Avenue, Chicago, Illinois 60637, USA. xvii + 520 pp. $28.00 U.S. + shipping (paperback).

Tropical habitats are especially rich in biodiversity, hard to study, poorly known, and threatened by human impact. *Neotropical Wildlife Use and Conservation* focuses on an attribute of the tropics that also is true of the entire earth: people are in them. This volume resulted from a seminar series convened by the editors at the University of Florida in 1987, inspired by A. L. Gardner's earlier presentation. Gardner's lucid Preface sets an overall tone for the book—well informed, empirical, and pragmatic—to which I shall return shortly. About 45% of the 47 authors are from Latin America. Editing and production are of the high quality we expect from this publisher. There are numerous graphs, and dozens of photographs portraying subjects as diverse and interesting as 16th century methods for collecting parrots, wild iguanas congregating at an artificial feeding station, and a lodge for ecotourists in Peru.

Six chapters directly address "reptiles" (exclusive of birds): Management of olive ridley sea turtles (*Lepidochelys olivacea*) nesting at Playas Nancite and Ostional, Costa Rica, by S. E. Cornelius, M. A. Ulloa, J. C. Castro, M. Mata del Valle, and D. C. Robinson; Economic analysis of sea turtle eggs in a coastal community on the Pacific Coast of Honduras, by C. J. Laguex; Effects of hunting on the reproduction of the Paraguayan caiman (*Caiman yacare*) in the Pantanal of Mato Grosso, Brazil, by P. G. Crawshaw, Jr.; The rational use of green iguanas, by D. I. Werner; An analysis of the spectacled caiman (*Caiman crocodilus*) harvest program in Venezuela, by J. B. Thorbjarnarson; and *Tupinambis* lizards in Argentina: implementing management of a traditionally exploited resource, by L. A. Fitzgerald, J. M. Chani, and O. E. Donadio. Amphibians are not treated. In addition to their primary concerns with conservation status and management, the chapters on reptiles are gold

mines of important new information on basic biology: female *Tupinambis* lizards remain with the nest throughout incubation (Fitzgerald et al.); female *Caiman crocodilus* in the Venezuelan llanos lead their young over distances of several kilometers to water (Thorbjarnarson).

Among 22 other chapters, those on hunting in South America by J. Marcio Ayres et al., R. A. Mittermeier, and W. T. Vickers document utilization of reptiles by indigenous people. Other "must read" chapters for anyone interested in conservation are those by K. H. Redford, J. G. Robinson, and J. H. Shaw on sustainable harvests of wildlife. M. J. Groom et al.'s analysis of prospects and problems associated with nature tourism, based on the author's experience in Manu National Park, is excellent.

This is a rewarding, thought-provoking book for anyone who has worked in the neotropics. It may shock those who still believe there are pristine places on earth and that conservation somehow can avoid incorporating humans as integral parts of the landscape. There are numerous photographs of hunters with dead monkeys and tapirs, and several authors make clear that "savages" can only remain "noble" if human population density is low. There are contradictory opinions about the domesticability of pacas, pitting a naturalistic perspective on what is "wild" against the surprising results of an ingenious experiment. There are assertions that large industries based on the hides of lizards (Fitzgerald et al.) and caimans (Thorbjarnarson) are profitable, sustainable, and desirable.

For biologists this book also has vignettes that induce frustration: In Mexico, how can it be so easy to hunt millions of doves or buy endangered cat skins, yet impossible to collect a few dozen common lizards for science? Another important issue is criticized explicitly in C. H. Freese and C. J. Saavedra's concluding chapter; they estimate that well over half of the information generated by "wildlife management research" goes unpublished, at best buried as "gray literature" in reports to agencies.

This is not a preachy book, but its overall messages are as important as the research findings and specific recommendations. Citizens of the richest nation on earth, we in the U. S. often presume to export ideals and practical strategies to other "less fortunate" cultures. Living in the San Francisco Bay Area, a hotbed of environmentalism, I find the hubris ironic at times: our regional park management lacks the political will to control feral cats that eat the lizards upon which threatened Alameda whipsnakes depend for food; animal rights groups thwart efforts to eliminate introduced red foxes, thereby hastening the extinction of clapper rails; William Devall, coauthor of *Deep Ecology*, tells a public gathering that chanting Native American songs at dawn is more important than recycling; and far too many believe that if we can just buy the land down there, we'll own the jaguars.

In *Neotropical Wildlife Use and Conservation*, several Latin American countries emerge as real heroes of conservation; there are lessons for everyone in their frustrations and successes. Although most land supporting wild populations will be used in some form by humans in the 21st century, as yet we haven't formulated widely accepted goals for conservation in that context and we know little about how disturbed ecosystems work. The pragmatic attitudes and approaches described in this book will help lead the way.

Gila Monster – Facts and Folklore of America's Aztec Lizard, by David E. Brown and Neil B. Carmony. 1991. High Lonesome Books, P.O. Box 878, Silver City, New Mexico 88062, USA. ISBN 0-944383-12-2. 127 pp. $8.95 (softcover).

Indians and other long-time residents of the American Southwest were aware of the gila monster well before its formal description by Cope in 1869. Cope discovered that a specimen at the Smithsonian Institution collected by the United States-Mexico Boundary Survey had been misidentified as *Heloderma horridum* (Wiegmann 1829). That species, the Aztec or beaded lizard of México, ranges from southern Sonora to Guatemala, whereas the gila monster, *H. suspectum*, is a resident of the Sonoran Desert, primarily of Arizona and northwest México.

The origin of its common name is unknown, but presumably refers to the Gila River where the animal was frequently encountered in the early days of Mexican and Anglo settlement. Conceivably, the name is a phonetic derivation of its Greek epithet *Heloderma*, which translates as "studded or beaded skin." These and numerous other facts and fables about America's most peculiar squamate are contained in this delightful little book by Brown and Carmony illustrated with 32 black & white photos, line art, and distribution maps. It is a modest production but the style and content are well-crafted.

Part I is a natural history sketch of the gila monster that brings together salient points from the scientific literature (listed in a separate bibliography) on the lizard's description, distribution, fossil record, subspecies, home range, habits, and venom. The treatment of these topics is brief but accurate. Part II is an entertaining journey into the curious myth and folklore that has followed the gila monster. Many tales are reproduced in the book as direct quotes from old newspaper accounts, magazine articles, and other archives from the Southwest. Not surprising, the gila monster's gaudy appearance and venomous properties were the basis for much of the mythology.

Indeed, that the gila monster is "poisonous" was disputed for many years, and several authorities of the day maintained that except for its powerful bite the animal was harmless. That mistaken view followed from the fact that venom was difficult to extract, and envenomation itself is accomplished not by enclosed, hollow fangs as in rattlesnakes, but through open grooves on the teeth. Not until after 1900, more than three decades since Cope's description of the species, was there conclusive evidence of the gila monster's capability. The venom is certainly potent, yet there are few if any credibly documented human fatalities from a gila monster bite. Still, the lore of the Southwest is replete with accounts that are supposedly true, as well as more fantastic claims such as: "the spot where the gila monster left that one drop of saliva can still be seen in the desert today, ten years later. All vegetation for a radius of 10 yards withered and died immediately and none new has ever grown here."

Once regarded with disgust and loathing, the gila monster today is a protected member of Sonoran Desert wildlife. This book is informative and lively reading. Anyone interested in these fascinating animals, or for that matter in Southwestern folklore, should pick up a copy.

Survey Of Academic Herpetology Programs

Faculty and staff at high schools, colleges, universities, zoos, and museums, as well as members of regional herpetological societies, are often asked by high school students to recommend an institution where they can begin training for a career in herpetology. There are a number of well known institutions that have major programs in this field and are the first to come to mind. However, many colleges and universities do not have a formal program in herpetology and offer only one course in the subject, with or without opportunities for undergraduate research. A student interested in herpetology can receive an excellent education at such institutions but may not submit an application for admission because the existence of a herpetology course at that location is not widely known.

This survey will attempt to correct this deficiency by compiling a list of colleges and universities that offer students some degree of training in the field of herpetology. The results will be made available (in a format to be determined) as soon as the data are compiled. If you are employed at an institution that offers a course/program in herpetology, please answer the following questions and return your responses to me. If you are not directly associated with a college or university but are aware of one or more institutions that has offerings in the area of herpetology, send me their names (a postcard will do) so they may be included in the survey; I will follow up on all such indirect references if no response is received directly from the named institution. I anticipate receiving many duplicate answers for this particular question (no. 9, below), but this may result in a few additional schools that might otherwise be omitted.

1. Name and address of college or university.

2. Name and telephone number of contact person at the above institution.

3. How many courses in herpetology are offered at the undergraduate level?

   a. How frequently are these courses offered?

   b. How many students are usually enrolled in the courses?

4. How many courses in herpetology are offered at the graduate level?

   a. How frequently are these courses offered?

   b. How many students are usually enrolled in the courses?

5. Do opportunities exist for undergraduate research in herpetology?

   a. If yes, is this research done under the guidance of and in conjunction with a faculty member?

   b. If yes, is this a formal part of the curriculum for which credit may be granted?

6. Can a student pursue a master's degree with a concentration in herpetology?

7. Can a student pursue a doctoral degree with a concentration in herpetology?

8. Please list the names of permanent faculty or staff who are doing herpetological research at this institution and give a brief statement of their research interests.

9. Please list the names of other smaller institutions that offer a course in herpetology.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in *HR*, but should be submitted to the *Journal of Herpetology* (see inside front cover for Editor's address).*HR* especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of *HR* for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Life History Notes, and Recent Population Changes appear in a recent issue of *HR* under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints (8 x 10 inch preferred).

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc., 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Life History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles, Techniques Articles, Points of View, as well as news notes and other material, should be sent to the Editor.

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of three reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Life History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in *HR* cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

RWH

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc. RFD 6 Box 1, Lawrence, Kansas 66046. *Herpetological Review* is composed using Microsoft Word and Aldus Pagemaker on Apple Macintosh computers. Camera-ready copy is produced on a Linotronic 230 Imagesetter at a resolution of 1700 dpi at Valley Type & Design, Fresno, California. All rights reserved. SOCIETY FOR THE STUDY OF AMPHIBANS AND REPTILES

NEW PRICE for the

Catalogue Of American Amphibians And Reptiles

The catalogue consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere.

COMPLETE SET: NUMBERS 1 - 505	$190.00
INDEX TO ACCOUNTS 1 - 400: Cross-referenced, 64 pages	$5.00
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$5.00
IMPRINTED POST BINDER: (note - two binders are needed for the 505 accounts)	$25.00
INCOMPLETE SET: NUMBERS 1 - 190	$60.00
191 - 410	$70.00
411 - 505	$60.00

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the ***Journal of Herpetology*** (4 issues annually), ***Herpetological Review*** (4 issues annually), and occasional issues of ***Facsimile Reprints in Herpetology***. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1992

Student member	$25.00*	Sustaining member	$60.00*
Regular member	$35.00*	Contributing member	$85.00*

Institutional subscription.....$60.00

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles***: subscription is $15.00 annually ($3.00 air delivery surcharge if airmail is desired.). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

Herpetology At The University Of Texas At El Paso

University of Texas at El Paso campus.

The University of Texas at El Paso ("Yoo-tep," *never* "Texas-El Paso") is the second oldest and third largest institutional component in the University of Texas system. Herpetology has been an active area at UTEP for the last thirty years, bolstered by many faculty and students who have employed amphibians or reptiles as research subjects during that period. Of the seventeen tenured and tenure-track faculty in the Department of Biological Sciences, more than half have published work on some aspect of the biology of amphibians and reptiles at some time in their careers. Moreover, several members of this faculty, including the ecologist W. P. MacKay, malacologist A. L. Metcalf, and paleobiologist A. H. Harris have recently pursued research projects that at least peripherally included amphibians and/or reptiles (see list of references). Seven individuals, however, constitute the historical and present-day core of herpetology at UTEP:

P. S. Chrapliwy: Pete Chrapliwy retired from the faculty in 1984 after twenty-five years of service at UTEP. Active in research herpetology early in his career, he later devoted his efforts to community service and teaching excellence. In fact, the University-wide student teaching award is named for him. At present he is one of our faculty *emeriti*, and still lives in El Paso.

L. N. Irwin: Louis Irwin, Chairman of Biological Sciences, joined the UTEP faculty in the Fall of 1991. His research interests focus on the gangliosides (cell membrane-imbedded glycolipids) found in amphibians and reptiles, and how the phylogenetic history of the pathways that produce these molecules interacts with environmental factors that influence their expression.

J. D. Johnson: Jerry Johnson, who earns his bread by serving on the faculty of the El Paso Community College, has an adjunct faculty position in the UTEP Department of Biological Sciences. In this latter capacity he carries out collaborative and independent research in the Department, liaises between the EPCC and UTEP at levels ranging from upper administrative to those of individual field courses, recruits students for our graduate and undergraduate programs, and teaches a course now and then. His research interests include systematics and biogeography of herps, especially those of southern Mexico; he is also co-chair of the SSAR Local Committee for the August 1992 meeting.

C. S. Lieb: Although he has been in and out of administrative, staff, and faculty assignments for the past eleven years, Carl Lieb anticipates beginning "normal" faculty life in the fall of 1992. Until then, however, his present duties are those of faculty member, coordinator of introductory biology laboratories, Director of the Indio Mts Research Station, and (in spare time) co-chair of the local committee for the August 1992 SSAR meeting. Active research projects include the systematics of anole lizards, evolutionary genetics of *Crotalus* venom proteins, and conservation biology of herps in the Rio Grande corridor.

E. D. Rael: Eppie Rael is an immunologist with a well-established research program involving the structure and function of snake venom proteins. He is not only concerned with biomedical implications and applications, but, in collaboration with Johnson and Lieb, is also vigorously pursuing studies of ontogenetic and populational variation in the five locally available species of rattlesnakes.

R. G. Webb: After thirty years of distinguished service at this institution, and after producing more than 100 scholarly publications in herpetology, Robert Webb has announced his retirement effective May, 1992. He will be continuing in an active *emeritus* capacity into the indefinite future, finishing up his monograph of the herps of Durango, México, and continuing several taxonomic projects on trionychid turtles, ranid frogs, and *Sceloporus* lizards of the *torquatus* group.

R. D. Worthington: Several years ago Richard Worthington deserted active herpetology for botany . . . but he still has his huge herp library, keeps up his memberships in herp organizations, and still contemplates an occasional herp research project. His future plans include working up parts of the amphibian and reptile material he collected during the year (1987) he spent in Malaysia on a teaching exchange program.

One of the supporting facilities for study of herpetology at UTEP is its collection of amphibian and reptile specimens, one of the six biosystematics collections of the Laboratory for Environmental Biology. This Laboratory is officially a research component of the Centennial Museum, the University's public-oriented museum of natural and cultural history. The herpetology collection, however, is housed in the Biology Building. The holdings consist of a modest 15,000 specimens, with synoptic breadth over much of the southern half of North America. Depth is mostly achieved only in regional material (primarily western Texas and southern New Mexico). The purposes of these collections reflect the past and present research interests of the faculty, as well as educational programs of the Department and the Museum. Components of this collection that might be of interest to portions of the SSAR membership include 1) a large proportion of R. G. Webb's Durango collection; 2) synoptic collections from Chiapas and the Isthmus of Tehuantepec made by J. D. Johnson; 3) R. D. Worthington's ambystomatid salamander collection, as well as his recent efforts in Malaysia; 4) Clayton May's Arizona collection (mostly lizards); and 5) over 1,000 dry osteological preparations of the regional herpetofauna. Specimen data for most of this collection are computerized, and information on UTEP holdings may be obtained free of charge by writing the Curator (Robert Webb).

Opportunities for field-oriented herpetology at UTEP are also enhanced by the University's commitments to the Indio Mountain Research Station (IMRS). This "station" consists of

a geographic area and set of facilities sponsored and managed by UTEP for research and education on the natural history of the Chihuahuan Desert. Station lands include 37,000 contiguous acres in southern Hudspeth County, Texas; the facilities consist of a small, rustic ranch house that provides shade, protection from the wind, and drinkable water.

Jerry Johnson measures frogs in the herp lab.

The Station terrain is dominated by a mixture of gently sloping bajadas and rugged slopes with limestone, sandstone, or conglomerate rock outcrops; elevations range from ca. 3200-5000 ft. Vegetation consists entirely of Chihuahuan Desert Scrub, especially catclaw acacia, lechuguilla, and arborescent yucca associations. The herpetofauna is heavy on the rattlesnakes (three species are abundant), and on the lizards with high thermal tolerance (it does get warm!). The area is completely uninhabited, and has not been used for grazing for at least ten years. The station is a three-hour drive from the UTEP campus; two hours to travel 120 miles on the Interstate, and then another hour for the last 20 miles over less than optimal roads. Once you are there, what is not accessible on the Station by 4x4 vehicles can only be reached on foot or horseback. In other words, the IMRS is a couch potato's hell and a field person's paradise. For details concerning access, contact the IMRS Director (Carl Lieb).

In the field at the Indio Mountain Research Station.

Given the size of the institution (ca. 17,000 students), the present economic difficulties for state-supported entities, and the mosaic devolution of academic biology nationwide, herpetology is fortunate to be holding its own at UTEP. We have the further advantage of our location, facilities, institutional mission, and a student population that appreciates the value of higher education. We thus look forward to the next thirty years with optimism and not a little excitement.

SSAR BUSINESS

Annual Report (1992) Of The Grants-In-Herpetology Committee

Committee: Dawn S. Wilson, University of South Florida; Joseph P. Ward, USAF; Charles W. Painter, New Mexico Department of Game and Fish; Carole L. Hom, University of California, Davis; Thomas H. Fritts, USNM; Maureen Donnelly, AMNH; Dale Belcher (Chair), Rio Grande Zoo.

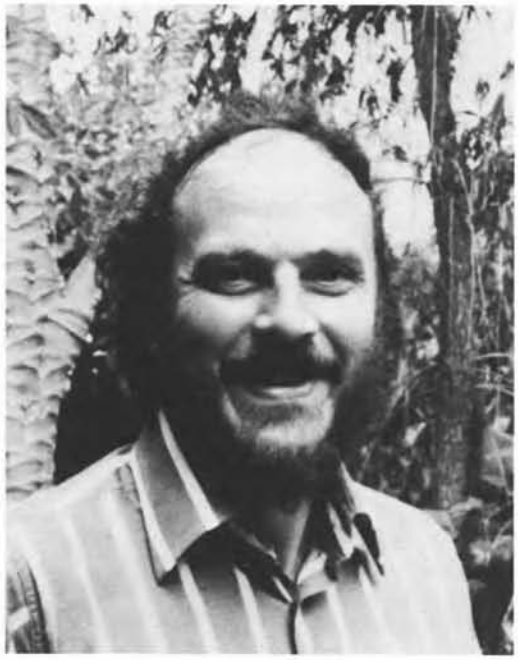
Five awards in three categories were made this year of $345 each, as follows:

1. Conservation—Marion R. Preest, Section of Ecology and Systematics, Corson Hall, Cornell University, Ithaca, New York 14853, USA. Title of proposal: Mechanisms of reduced growth rates in acid-exposed larval salamanders.

2. Field Work—Brian P. Butterfield, Department of Zoology and Wildlife Science, 331 Funchess Hall, Auburn University, Auburn Alabama 36829-4201, USA. Title of proposal: The pattern of morphological and genetic variation of selected members of the introduced herpetofauna of Florida.

3. Field Work—Christopher L. Parkinson, Department of Biology, University of Louisville, Belknap Campus, Louisville, Kentucky 40292, USA. Title of proposal: The relationships within the *Agkistrodon* complex (Viperidae: Crotalinae) as determined by DNA-DNA hybridization.

4. Graduate Student Research—Debra L. Holland, Department of Biology, P.O. Box 42451, University of Southwestern Louisiana, Lafayette, Louisiana 70504-2451, USA. Title of proposal: Prey detection via substrate chemical cues.



5. Graduate Student Research—Paul A. Stone, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA. Title of proposal: Sexual selection in lava lizards (*Tropidurus* spp.): a pilot study.

IN MEMORIAM

J. W. Patterson (1944 – 1991)

Jeremy W. Patterson, a well-known specialist on the physiological ecology of reptiles and biology of tropical African reptiles, died in London on 24 July 1991 of an inoperable brain tumor. Jerry was born 31 December 1944 in Croydon, England, and his interest in reptiles began at a young age, as shown by his well-thumbed and annotated copy of Malcolm Smith's "The British Amphibians and Reptiles" that is dated 1957. He graduated with honors in zoology from St. Catherine's College, Cambridge, in 1967 and earned both a masters and doctorate in medical parasitology at the School of Hygiene and Tropical Medicine, University of London, the latter degree completed under the supervision of D. S. Bertram. His thesis results, on the influence of juvenile hormone mimics on metamorphosis and fertility in mosquitoes, were published in a long series of papers in *Journal of Insect Physiology*.

But Jerry's real passion was herpetology, to which he returned in 1974 while on a postdoctoral fellowship with

Peter Davies at University of Nottingham. This collaborative work led to a large number of papers on the thermal biology of lizards, most notably a paper on thermal acclimation in temperate lizards in the British journal *Nature* (1978).

In 1977 Jerry emigrated to Southern Africa where he spent the rest of his scientific career, first at the University of Zambia, later at University of Malawi and finally, in 1989, to the University of Zimbabwe in Harare. Initially, his work in Africa dealt with thermal adaptations in reptiles, but he later shifted to ecological energetics, faunal studies, and general natural history.

Jerry's work was becoming widely recognized at the time of his premature death. He presented an invited paper on glycogen and lipid cycles in lizards at the First World Congress of Herpetology in Canterbury, England, in 1989, and the many biologists who met him there will remember the high standard of his work and his collegiality. We greatly mourn his loss.—Kraig Adler.

NEWSNOTES

Declining Amphibian Populations Program: California–Nevada Working Group

The California/Nevada Working Group met for the first time at Point Reyes National Seashore on 4 February 1992. The group was chaired by Gary M. Fellers and included fourteen representatives from the National Park Service, U.S. Forest Service, University of Nevada–Las Vegas, St. Mary's College, University of California–Davis, University of California–Los Angeles, California Academy of Sciences, California Department of Fish and Game, and the U.S. Fish and Wildlife Service.

James Vial gave an overview of the Declining Amphibian Populations program (under the auspices of the IUCN/SSC).

Each member of the working group provided a short summary of their research relating to amphibians. Most of the summaries provided compelling evidence for dramatic declines in amphibian populations throughout all or part of a species' range. Though some of the losses were from obvious causes (e.g., habitat loss), there were numerous cases where declines had occurred for no clear reason. David Bradford presented strong evidence that acid precipitation was not the cause of the declines, though it might be acting in concert with other environmental stresses.

The status of the Smithsonian handbook (for monitoring amphibian populations) was discussed at some length. Further discussions centered on the need to gather data that are comparable across various studies. A data form used by the USFWS was examined in detail with the goal of determining the minimum amount of data that should be collected as part of any amphibian field study. A proposed minimum standard will be developed by the working group and a sample form will be made available to the community of amphibian field biologists.

GARY M. FELLERS
Point Reyes National Seashore
Point Reyes, California 94956, USA.

Collections Transferred To The California Academy Of Sciences

The Department of Herpetology, California Academy of Sciences, recently acquired parts or all of the following herpetological collections: California State Department of Fish and Game (CDFG); University of California at Riverside (UCR); University of Houston (UH); University of Montana, Missoula (UMM); and a series of *Sauromalus* from Portland State University (PSU).

A total of 2,411 specimens have been catalogued (see table below). Noteworthy collections consist of: 225 specimens from Bulgaria; 608 *Anolis* from Antigua, Dominica, Nevis, Saint Croix, Saint John, and Saint Martin; 116 *Crotalus* from the western United States, and 153 specimens from California's Central Valley.

	Salamanders	Frogs	Lizards	Snakes
CDFG	61	26	17	130
PSU	–	–	484	–
UCR	10	7	661	–
UH	4	808	4	139
UMM	9	42	1	8

The CAS herpetological collections are completely computerized. We welcome reasonable requests for information about our holdings. For further information on these collections or other material in the Department, please contact Jens V. Vindum, Collection Manager, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA, telephone (415) 750-7037.

Manuscripts Solicited

The Society for Northwestern Vertebrate Biology (SNVB) is an association of biologists studying amphibians, reptiles, birds, and mammals in northwestern North America. *Northwestern Naturalist*, formerly *Murrelet*, is published triannually by Allen Press; recent volumes have totalled over 100 pages annually. The *Northwestern Naturalist* welcomes original contributions dealing with the biology of birds, amphibians, reptiles, and mammals in the region defined as Alaska, Yukon, District of MacKenzie, British Columbia, Alberta, Saskatchewan, Washington, Oregon, Idaho, Utah, Montana, Wyoming and Colorado west of the Great Plains; and Nevada and California north of the Mojave Desert. Manuscripts may be submitted as feature articles or general notes. All manuscripts are peer-reviewed. The journal strives for high standards and consequently has a significant rate of rejection. There has been a dearth of herpetological manuscripts, so this announcement is a reminder to those working in the Northwest that *Northwestern Naturalist* is a quality outlet with a moderately fast turn-around time. Manuscripts or requests for instructions for contributors should be directed to the Editor:

Stephen Corn
Editor, *Northwestern Naturalist*
U.S. Fish and Wildlife Service
4512 McMurry Avenue
Fort Collins, Colorado 80525-3400, USA.

Nixon Griffis Fund For Zoological Research— 1991 Grant Recipients

The Nixon Griffis Fund for Zoological Research (NGFZR), established in 1984 by New York Zoological Society Trustee Nixon Griffis, awarded six research grants on 10 December 1991. Three of the awards involved research on herpetological subjects, as follows:

Julian Duval, Indianapolis City Zoo, Scott Davis, and Edward Louis, Jr., Texas A&M University — "Subspecies Identification of the Grand Cayman Iguana (*Cyclura nubila lewisi*)."

Gary Ferguson, Texas Christian University, Richard Hudson and Stephen Hammack, Ft. Worth Zoological Park — "Effects of Varying Vitamin/Mineral Supplementation on the Growth, Adult Size, and Reproduction of the Panther Chameleon, *Fucifer (Chamaeleo) pardalis*."

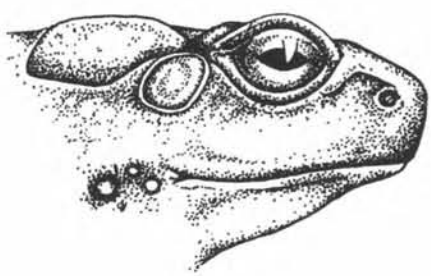
James Jacobson, University of Houston, Joseph Flanagan, Denton A. Cooley Animal Hospital, Houston Zoo, and Stanley Mays, Houston Zoo — "Determining Sperm Retention and Parentage of African Spurred Tortoises (*Geochelone sulcata*), Using DNA Fingerprinting."

Nixon Griffis Fund for Zoological Research grants are available to members of the zoo and aquarium community. Fund recipients may be keepers, curators, veterinarians, or research and consulting biologists. Grants, not to exceed $3000, are awarded semi-annually. Closing periods are January 1st and July 1st. For information about the Fund and grant application procedures, contact John Behler, Coordinator, Nixon Griffis Fund for Zoological Research, c/o New York Zoological Society, Bronx Zoo, Bronx, New York 10460, USA.

Call For Student Proposals

The Gopher Tortoise Council is seeking proposals from undergraduate and graduate students who are planning or actively conducting research on the gopher tortoise (*Gopherus polyphemus*). Proposals that undertake pertinent research on upland habitats within the range of the gopher tortoise will also be considered. A maximum of $400 is available.

Proposals should be no more than four typed, double-spaced pages and should include a description and justification for the research, a budget indicating how the money will be spent, and a brief biographical sketch. Deadline for receipt of the proposal is 31 August 1992.



Proposals should be submitted to:

Dr. Bob Herrington
Student Awards Coordinator
Department of Biology
Georgia Southwestern College
Americus, Georgia 31709, USA.

Researchers' Paradise!

There has never been a greater need to study and preserve tropical ecosystems and their inhabitants than the present. Cano Palma Biological Station, located on the Caribbean coast of Costa Rica, is situated in a biological corridor between two national wildlife preserves. This virtually unstudied habitat, combined with that in adjacent Nicaragua, constitutes the largest tract of lowland tropical rainforest outside the Amazon basin. Wildlife census studies in the region document more than 100 species of reptiles and amphibians to date and much is unstudied. The station is located on ca. 750 acres bordered on two sides by rivers and on the remaining sides by rainforest. There is accommodation in dormitory style facilities for 12 people at a time with showers and toilet facilities available, plenty of potable water, and kerosene illumination. Electricity will installed in early 1992, along with a back-up generator. Cano Palma station is accessible only by river boat or small plane. It is administered by a non-profit group which accepts inquiries:

Canadian Organization for Tropical Education
and Rainforest Conservation (COTERC)

MEETINGS

Second World Congress Of Herpetology

The Second World Congress of Herpetology will be held 29 December 1993 to 6 January 1994 in Adelaide, Australia. The Congress organizers would appreciate the timely return of the Provisional Registration Form from those persons planning to attend. Bookings for accommodations and possible arrangements for charter flights require accurate estimates of attendance. Those who have not received the pre-registration form but wish to do so should contact the Congress Director:

Michael J. Tyler
University of Adelaide
Department of Zoology
Box 498 GPO
Adelaide, South Australia 5001
Australia.

ASC Annual Meeting

The Association of Systematics Collections will hold its 1992 Annual Meeting in conjunction with the American Institute of Biological Sciences on 9-11 August 1992, in Honolulu, Hawaii. Featured events will be a workshop on "Data Sharing and Database Ethics," an informational session on "Systematics Agenda 2000" (the effort to determine research needs and priorities in systematics), and a discussion of the role of vice presidents for research at natural history institutions. A business meeting and discussion of NSF programs will be held on August 9th. For program information, contact:

ASC
730 11th St NW, 2nd Floor
Washington, DC 20001, USA
Tel: (202) 347-2850.

Organization Of A Symposium On The Conservation Of Florida Turtles

The Gopher Tortoise Council is requesting input from interested parties on the organization of a "Symposium on the Conservation of Florida Turtles." Over the last few years, several turtle biologists and conservationists have discussed the need for and possibilities of such a meeting. Interest in this subject has been expressed by conservation organizations, the environmental education community, and outdoor and environmental reporters/writers. The main intent would be to bring these groups together for the benefit of Florida turtle conservation. Persons interested in participating in such a meeting or wanting to exchange ideas should contact:

George Heinrich
Gopher Tortoise Council
P.O. Box 61301
St. Petersburg, Florida 33784-1301, USA.

AAZPA Herp Advisory Group Meeting

The Mid-Year Meeting of the American Association of Zoological Parks and Aquariums (AAZPA) Herpetological Advisory Groups will be hosted by the St. Louis Zoo, 21 - 23 June 1992. Anyone interested in additional information should contact:

Ron Goellner
Chairman, SSAR Zoo Liaison Committee
St. Louis Zoo
Forest Park
St. Louis, Missouri 63110, USA
Tel. (314) 781-0900
FAX: (314) 647-7969.

REGIONAL SOCIETIES

German Journal *Sauria* Now in English

Among terrarium-keepers, *Sauria* is known for its high quality and useful information. This German journal is published by the Society Terrariengemeinschaft Berlin. It is now produced in an English version, *Sauria (E).*

The first volume contains 176 pages (four issues + supplement), and costs $38.00 US. Subscription can be made to the following address:

HERPRINT INTERNATIONAL
P.O. Box 14117
Bredall 1623
R.S.A., South Africa.

Subscriptions to the German version are available for $22.00 US or DM 34.00 from:

TGB-Sauria
Peter Grossmann
Lepsiusstr. 53
D(W) - 1000 Berlin 41
Germany.

New Regional Societies

Please make note of the following new regional herpetological societies:

Chihuahuan Desert Herpetological Society
c/o Paul Hyder
Department of Biology
New Mexico State University
Las Cruces, New Mexico 88003 USA.

Utah Association of Herpetologists
195 West 200 North
Logan, Utah 84321-3905, USA.

San Joaquin Herpetological Society
P.O. Box 1104
Clovis, California 93612-1104, USA.

In addition, please note address or structural changes in the following groups:

California Turtle & Tortoise Club
P.O. Box 7300
Van Nuys, California 91409-7300, USA.

Oklahoma Herpetological Society
Oklahoma City Chapter
Oklahoma City Zoo
2101 NE 50th
Oklahoma City, Oklahoma 73111, USA.

Oklahoma Herpetological Society
Tulsa Chapter
5701 East 36th Street North
Tulsa, Oklahoma 74115, USA.

The Dallas Herpetological Society is no longer extant.

Regional society officers are encouraged to submit address changes to the SSAR Regional Society Section Editor (see inside front cover of HR) and new societies are invited to announce their existence in this column. Established groups are also invited to submit short descriptive articles about their societies for publication in this column.

ARTICLES

Criddle's Riddle: Where Do Young Garter Snakes Hibernate?

Studies of northern populations of garter snakes (*Thamnophis* spp.) indicate that parturition occurs away from communal dens, and that the majority of neonates (and yearlings) spend their first few winters hibernating in sites other than those used by adults (Gregory 1977, Larsen and Gregory 1989, MacMillan 1988). Exactly where overwintering of neonates occurs is unknown, although some clues are available. In 1937, Stuart Criddle published a short note describing the presence of 257 small snakes (*Thamnophis radix*, *Storeria occipitomaculata*, and *Opheodrys vernalis*) in an active mound of the ground-nesting ant genus *Formica*. Garter snakes and other reptiles and amphibians hibernating in ant mounds have also been reported by Carpenter (1953), Sharplin (1966), Lang (1971), and Roberts (pers. comm.).

If neonatal and juvenile garter snakes are able to rely on ant mounds as hibernacula, it would account for their absence from adult denning populations. In at least two ways, ant mounds seem to represent optimal hibernacula. Mounds of ground-nesting ant species are ubiquitous throughout the range of northern snakes, thus minimizing the distance snakes would have to travel to secure suitable hibernacula (distances between summer habitat and adult hibernacula may be quite extensive; Gregory and Stewart 1975, Larsen 1987). Further, northern ant colonies that persist over winter probably possess a mound that provides protection from sub-zero temperatures, as to our knowledge, freeze tolerance in ants has not been documented.

Given the abundance of ant mounds present in or near snake habitat, searching for hibernating snakes via haphazard excavation of mounds would be destructive, and quite possibly fruitless. Current technology does not permit radio-tracking of animals the size of neonatal or juvenile garter snakes. Hence, investigation into the relationship between overwintering snakes and ant mounds must come from fortuitous observations or experimental manipulation. Herein we report the results of a preliminary experimental study on the use of ant mounds as hibernacula by neonatal snakes. Our goal was to examine the overwinter survivorship of neonatal snakes in active ant mounds relative to those in subterranean pits of rock fragments. Although our results are not conclusive, we present our method for study, and the results thereof, in the hope that they will provide a basis for future investigations.

Ant mounds were established by excavating queenright colonies of *Formica fusca* in the field during mid-September (1988) and transporting them in 20-litre buckets to enclosures in a previously cultivated field at the University of Alberta farm (Edmonton, Alberta). The enclosures (1.55 m long by 0.6 m wide by 0.25 m high) were constructed using plywood (implanted ca. 5 cm in the ground) that was smeared on the inside upper 5 cm with petroleum jelly to prevent ants from emigrating (Hölldobler and Wilson 1990). One colony was established in each enclosure by digging a hole to approximate the depth and diameter of the transplant mound, and placing the original mound (soil and ants) in that excavation. We observed that the ants in all 15 enclosures reconstructed their mounds, and within two weeks of transplantation the "new" mounds appeared typical of those seen in natural settings. All 15 colonies survived the first winter, and throughout the ensuing spring and summer, the colonies were fed approximately 5 g of an ant diet (Bhatkar and Whitcomb 1970) and one *Tenebrio molitor* larva every three days. Seven of the 15 mounds became inactive during the summer (subsequently referred to as "failed" mounds), and three of those mounds were tunneled into by voles (*Clethrionomys* sp.). Prior to fall, Green Cross™ Ant Killer was administered to the active colonies in an attempt to extirpate those colonies. However, that protocol proved unsuccessful in extirpating ants from active mounds. Three of the seven "failed" mounds were excavated, and the soil replaced with an assortment of rock, brick and concrete fragments to a depth of 50 cm. Approximately 10 cm of soil was placed over each of those "rubble hibernacula." Soil was also repacked along the enclosure bottoms, particularly in areas subjected

to vole tunneling. Thus, three replicates of three potential hibernaculum "types" were available for overwintering by immature snakes: active ant mounds, vole-tunneled mounds (without ants), and rubble hibernacula. Thermocouple probes (Macartney et al. 1989) were implanted into one replicate of each of the three hibernaculum types and wire screen was placed over the enclosures to exclude avian predators.

Neonatal garter snakes were obtained by collecting gravid females and allowing them to give birth in captivity. Prior to their introduction into the enclosures, the neonates were kept outdoors in a terrarium (exposed to seasonal temperature and photoperiod), given *ad libitum* access to diced earthworms (*Lumbricus terrestris*), and marked individually using indelible felt pens. On 28 September 1989, groups of 13 (two enclosures) or 11 (one enclosure) neonatal snakes were placed into three enclosures of each of the three hibernaculum types. During the next two days we observed the neonates investigating, entering, and emerging from the ant mound and rubble hibernacula. We witnessed individual snakes being attacked by small numbers of ants in the active ant mound condition; however, live snakes were observed protruding from the tunnels of the active ant mounds during that period. By 30 September, sub-zero air temperatures (°C) prevailed, and thereafter snakes were not observed. No evidence of vole-tunneling under any of the enclosure walls was observed prior to the first snow fall. Ambient air temperatures and sub-surface probe temperatures were recorded once a week throughout the winter.

By spring 1990, we became aware of two potential problems: i) inadequate drainage and drifting snow resulted in meltwater accumulation in several enclosures, and ii) during winter, voles continued to tunnel under enclosures, thus allowing snakes to move between or exit the enclosures altogether after emergence. The latter problem, coupled with our inability to continually monitor the enclosures during spring, rendered it impossible to ascertain the number of snakes emerging from each hibernaculum type. Only six of the 111 snakes originally introduced to the enclosures were recovered. Those six animals were apparently killed and were partially devoured by ants upon emergence. However, the markings on five of the snakes were still discernable. All of those snakes had presumably overwintered in ant mounds, with four of the five identifiable snakes overwintering in mounds which had been subjected to vole tunneling, and the fifth overwintering in an active ant mound. Temperature profiles did not differ among the three hibernaculum types as a maximum difference of 2°C (equivalent to measurement error) was recorded within depths over all readings. Our temperature records indicated that sub-zero temperatures were experienced no deeper than 51 cm below ground surface in all three of the hibernaculum types, so presumably the animals overwintered below that depth in vole-tunneled ant mounds or the active ant mound. Successful overwintering in rubble hibernacula would have been unlikely since those excavations extended only 50 cm below the surface, although garter snakes have been shown to tolerate short-term exposure to freezing temperatures (Costanzo 1988, Costanzo et al. 1988).

Despite the poor recovery of snakes, we find our results encouraging in that they provide evidence that neonatal snakes can survive overwinter in ant mounds, despite the somewhat unnatural conditions of our study. Given that observation, it would seem logical that natural mounds would afford safe hibernacula. Whether or not mounds with extinct ant populations are preferred to active mounds is unclear as snakes and frogs have been excavated from both active and inactive mounds (Carpenter 1953, Criddle 1937, Noble and Clausen 1936, Roberts pers. comm., Sharplin 1966). Further, work by Costanzo (1986, 1989) has indicated that successful overwintering by garter snakes is facilitated by partial or even total submergence in water. The deepest chambers in ant mounds may coincide with the water table, allowing snakes to avoid desiccation. Indeed, Criddle (1937) observed that some of the hibernating snakes he excavated had positioned themselves in standing water.

We believe more definitive results could be obtained by i) placing the artificial enclosures on a south-facing slope, thereby maximizing exposure to the sun in spring and ensuring adequate drainage, ii) preventing microtine rodent invasion of the enclosures by constructing a more effective barrier, iii) initiating more intensive ant extirpation at an earlier date, and iv) monitoring the enclosures regularly during the spring emergence period. We hope researchers will be encouraged to conduct further experiments of this nature, thereby increasing our knowledge of the life-history of neonatal snakes.

Acknowledgments.—Funding for this study was provided by a University of Alberta Central Research Fund grant and Natural Science and Engineering Research Council of Canada post-graduate scholarships to KWL and JFH. We thank E. R. Hare for caring for the ant colonies during the summer of 1989, and D. Farr, P. T. Gregory, W. R. Roberts, and J. O. Murie for providing comments on an earlier manuscript. M. A. Price and T. Macdonald facilitated access to the University's experimental farm. We also thank B. Letcher and W. J. Gallin for supplies, J. P. Costanzo for valuable input, and C. L. James, E. R. Hare, F. S. Chia, C. R. James, R. E. Peter, R. A. Ring, and B. L. Scarfe for support throughout this study. We are indebted to our respective supervisors, Stan Boutin and Jan O. Murie, for supporting this brief herpetological/entomological excursion outside the realms of our mammalogical dissertations.

Abronia chiszari (Reptilia, Anguidae), A Second Specimen From The "Los Tuxtlas" Region, Veracruz, México

Two species of *Abronia* have been reported from the "Los Tuxtlas" region of Veracruz: *A. reidi* Werler and Shannon and *A. chiszari* Smith and Smith (Pérez-Higareda et al. 1987). *Abronia reidi* is known from two specimens collected in the cloud forest at the rim of Volcan San Martín (Werler and Shannon 1961). *Abronia chiszari* was described from a single juvenile specimen collected on the rear bumper of a car in low cloud forest near Cuetzalapan, in the Santa Marta volcanic range (Smith and Smith 1981). Because *A. chiszari* is very similar to *A. bogerti* it has been suggested that *A. chiszari* could be conspecific with *A. bogerti* except for their difference in distribution and habitat (Good 1988; Smith and Smith 1981). The purpose of this note is to validate *A. chiszari* and provide morphological and ecological information on an additional individual.

The specimen reported here was collected on 4 June 1986, just after it fell onto the windshield of a moving truck, in the transition between tropical rain forest and cloud forest (Benabib and Congdon, in press) in Bastonal, Santa Marta volcanic range, Municipality of Catemaco, Veracruz, ca. 800 m elevation. On 17 July one of us (RCV) returned to the site and climbed 20 m into a large *Ulmus mexicanus*. Two other *Abronia* were seen at about 10 and 18 m, but were not captured. The general habitat where the specimen was collected was similar to that described by Smith and Smith (1981) for the holotype. Our specimen, a mature male, has a SVL of 74.4 mm, a tail length of 115 mm (tail tip regenerated), a head width of 9.7 mm, and weighed 5.25 g in life. The specimen is deposited in the Herpetological Collection at the Biological Station of Los Tuxtlas (UNAM-LT 3151).

Table 1. Selected characters of *A. chiszari* (data from Smith and Smith 1981), compared with *A. bogerti* (data from Tihen 1954), its closest relative.

Characters	*bogerti* (holotype)	*chiszari* (holotype)	*chiszari* (UNAM-LT 3151)
Transverse rows of dorsal scales	41	41	46
Longitudinal dorsal scale rows	14	16	15-16
Scales on nape region fewer than	8	7	8
Anterior temporals	2	3-3	3-3
Anterior internasals	2	2	2
Supraoculars	5-3,5-4	5-3	5-3
Supralabials	9-10	9-9	9-9
Infralabials	?	8-8	9-9
Scale whorls on tail	105	?	99*
Dark bands on body	10-11	11	11
Bands on tail	?	?	14-15

*regenerated tail

This specimen resembles the holotype illustrated by Smith and Smith (1981), and all of the diagnostic characters agree with those given in the type description. A comparison of characters between the holotype specimens of *A. chiszari* and *A. bogerti* and the specimen reported here are given in Table 1.

Smith and Smith (1981) discussed the similarity of *A. chiszari* to *A. bogerti* in several characters. Our specimen possesses characters that clearly separate it from *A. bogerti*. For example, our specimen of *A. chiszari* has the cantholoreal separated from the frontonasal by contact of the prefrontal and canthal, and the upper two primary temporals are relatively smaller than those of *A. bogerti*, as predicted by Smith and Smith (1981, p. 54). Also, the specimen from Los Tuxtlas has prefrontal-anterior superciliary contact on both sides, a characteristic that could be diagnostic of the species (Good 1988). The number of longitudinal dorsal scale rows and scale whorls on tail may be other differences (see Table 1). Besides the dark bands on body and tail, the ventral surface is white with small dark marks, the ventral surface of the head is immaculate, and

the dorsal head scales are gray with dark edges. Although this pattern is similar to that of *A. bogerti*, our specimen is an adult; we do not know if the coloration in the juvenile *A. chiszari* is different. Other characters are similar to *A. bogerti* as discussed by Smith and Smith (1981) and Good (1988).

In the context of other *Abronia* species *A. chiszari* seems to be a good member of the *deppii* species group as defined by Good (1988). The characters that clearly separate *A. chiszari* from other *Abronia* species are the higher count on transverse dorsal scale rows, 41 and 46 in the two known specimens, and the prefrontal-anterior superciliary contact. The habitat where *A. chiszari* occurs also is very atypical for a member of the genus (see below).

All known *Abronia* species are allopatric (Good and Schwenk 1985), and are associated with pine-oak and cloud forest communities. It is not surprising to find two species of the genus within the Los Tuxtlas region, one at San Martín and the other on Santa Marta. Although the two localities are only 20 km apart, they are separated by low elevations and different vegetation structure. Smith and Smith (1981) also discussed the possible distribution of *A. chiszari* within the Sierra de Los Tuxtlas. We do not believe that this species ranges beyond the Sierra de Santa Marta, where the transition between tropical rain forest and cloud forest seems to be restricted to lower elevations; further, rainfall is higher than in other localities (>8000 mm/yr, Benabib and Congdon, in press) within the Los Tuxtlas range. We are convinced that there is a complete segregation of both species of *Abronia* in the Sierra de Los Tuxtlas. Other differences exist in the herpetofauna at the two localities. For instance, each range has distinct and different species of the genera *Lepidophyma*, *Sibon*, and *Eleutherodactylus*.

Acknowledgments.—We are grateful to Santiago Sinaca for collecting the specimen and climbing into the canopy looking for others, and to Gonzalo Pérez-Higareda for providing the catalog number of the specimen discussed here. The corrections and recommendations of David Good, C. J. McCoy, and an anonymous reviewer are much appreciated.

POINTS OF VIEW

The Evolutionary Species Concept: A Reply To Van Devender et al. And Montanucci

Van Devender et al. (1992) and Montanucci (1992) have criticized my recent article (Collins 1991) in which I use the Evolutionary Species Concept (ESC) to define 55 allopatric, differentiated subspecies as species. I here rebut those criticisms.

VAN DEVENDER ET AL.

Van Devender et al. (1992), in their opening paragraph, state that "apparently field or museum specimens were not examined [by me] and [my recommended] changes were based on distribution maps and current subspecific status." Use of the word "apparently" in that statement is an attempt to bias readers into thinking that it was somehow necessary for me to examine field or museum specimens. In fact, the 55 subspecies in my list were already diagnosed (based on field and museum specimens) in their original descriptions and most had been accepted as legitimate taxa for many years—if they had not been so diagnosed, they would not be recognized at all. In addition, I determined from the best available published maps that they were also allopatric, and I chose the conservative interpretation that they were historically independent lineages (= species), not the radical and imparsimonious conclusion that they were "conspecific" (in the non-historical sense of Ernst Mayr) with other allopatric, distinctive, and historically isolated populations. My elevation of the 55 taxa to specific status was not arbitrary; my criteria were clearly stated. Further, my list was logical because all taxa on that list fulfilled the requirements for specific status using the Evolutionary Species Concept (as proposed and defined by Wiley 1978). In other words, each was (according to published sources) allopatric, each was (according to published sources) distinct (morphologically and/or genetically), and, without resorting to unwarranted assumptions, each was assumed to have its own evolutionary fate. A taxon on my list would have been ineligible for consideration only if the original description was flawed (i.e., based on errors), or if there were unpublished distributional data that showed the nominal taxon to intergrade smoothly with a nearby population. I accept no responsibility for being unaware of unpublished distributional data, but I suspect that the distributional gaps separating the 55 allopatric populations from their presumptive nearest relatives are real, and not an artifact of collecting. Further, if the original diagnoses of some of the taxa on my list are shown to be wrong, then they should not have been recognized (as subspecies or anything else) in the first place.

Van Devender et al. (1992) contend that it is incorrect to elevate to species status *Coluber mormon* because of evidence presented by Greene (1984) and Corn and Bury (1986). Frankly, I think this is an open question. I reject the taxonomic conclusions of Greene (1984) because of the small sample sizes for each of his isolated populations. Corn and Bury (1986) described an isolated, distinct population of *Coluber* in western Colorado and adjacent Utah, using a sample of only 11 specimens. Because this isolated population is located between the ranges of *mormon* and *flaviventris*, they assumed that *mormon* did not deserve specific status and that *Coluber constrictor* was, therefore, a single transcontinental species. I disagree and feel, based on their data, that the isolated population in western Colorado and adjacent Utah is likely a distinct species, a conservative conclusion rather than the radical one by Corn and Bury (1986) which assumes a relationship with other morphologically different, genetically isolated populations.

Van Devender et al. (1992) disagree with my recognition of *Tantilla cucullata* and *T. diabola* as species. They cite Degenhardt et al. (1976) as evidence that *cucullata* and *diabola* are the same species, but fail to note that those authors stated (p. 233) that in the western (Big Bend) populations (*cucullata*) the "white neck-ring is broken at the dorsal midline in all [specimens]" whereas in the Devil's River (eastern) populations (*diabola*) the "white neck-ring is continuous across the middorsal line." The neck-ring character shows no overlap among the two taxa, and thus, Degenhardt et al. (1976) made a very strong case for specific recognition of *Tantilla diabola* and *T. cucullata*. Van Devender et al. ask "would the Big Bend population with characters of both *cucullata* and *diabola* warrant full species status?" Probably not, but since *T. diabola* populations are the only ones with continuous neck-rings and do not share that character with *T. cucullata*, the question is irrelevant. Apparently *diabola* and *cucullata* are 100 per cent different based on the data presented by Degenhardt et al. (1976). Recognizing both populations at the specific level is certainly the most conservative conclusion based on evidence. Van Devender et al. assume that *diabola* and *cucullata* are conspecific; that conclusion is unscientific, because it does not rest on either distributional or phylogenetic evidence.

Van Devender et al. (1992) next discuss *Lampropeltis alterna*, although it is irrelevant to my article because it did not qualify for my list. They ask whether "'species' revert to 'subspecies' when intermediate specimens are found in intervening areas." My answer is: The recognition of taxa stems from evidence; if evidence is augmented or corrected, sometimes conclusions have to change. Since this is a discovery process (something I think Van Devender et al. would agree with) rather than invention, I don't really know whether to take their question seriously. However, just filling in a distributional hiatus does not ensure that two populations are conspecific. Also, to set the record straight, Collins (1990) did *not* follow Garstka (1982) in elevating *L. alterna* to specific status, as stated by Van Devender et al. That taxonomic change was accomplished by the vote of a group of snake systematists (see Collins 1990: p. 2).

Van Devender et al. (1992) disagree that *Lampropeltis pyromelana infralabialis* should be given specific status. Inclusion of this nominal taxon in my list of 55 species was based on the assumption that it was diagnosable and determined to be distinct. But apparently Van Devender et al. feel the characters which are the basis for recognizing it are suspect. I have no argument with this, because they have greater familiarity than I with this population. If the characters that supposedly distinguish *L. p. infralabialis* are not diagnostic, then its evidential support is flawed and it does not deserve even subspecific status. The same holds true for all other subspecies, not just those of *L. pyromelana*. Van Devender et al. are impressed that *L. pyromelana* north of the Grand Canyon differs so little after (minimally) 10,000 years of isolation. So am I,

and I recommend that it not be recognized as a subspecies, but instead just for what it really is, an undifferentiated northern population of the wide-ranging species *L. pyromelana*. Van Devender et al. also state that "strangely, according to these authors [Collins 1991; Frost and Hillis 1990], subspecies are apparently not included in biodiversity." While I never made that statement, it is definitely true. I have never seen a published work on biodiversity that equates species with subspecies, and for that reason the number of real species in the subspecies-heavy North American herpetofauna has been woefully underestimated.

Van Devender et al. (1992) disagree that the various races of *Lampropeltis zonata* should be given specific status, yet they provide no evidence that these populations are conspecific by any definition, nor do they demonstrate with proof that they are all even each other's closest relatives. They do cite as evidence a single "intergrade" specimen from an intermediate mountain range, a specimen that could just as easily be called a relictual hybrid between two distinct species. A single hybrid specimen is very weak proof of close relationship, so provided the differentiation is not a statistical artifact, these various populations of *L. zonata* are clearly independent evolutionary lineages (= species). If the interpopulational differences, however, are only artifacts of sampling, then none of the populations should be recognized at any level—they would then simply represent undifferentiated populations of a single species, *L. zonata*. The statements on past isolation and glacial patterns by Van Devender et al., while interesting, have no bearing on the evolutionary fate of *L. multifasciata, L. parvirubra,* and *L. pulchra* (or necessarily on their past; the estimates by Van Devender et al. for last interpopulational interchange are necessarily restricted to the last time they *could* have exchanged genes). Each is apparently a distinct, allopatric population, and they deserve recognition as evolutionary entities. Any other taxonomic arrangement would be unscientific, since its conclusions would be based on assumptions about an unproven past and an unknown future, conclusions that could be obtained with similar accuracy by reading tea leaves.

Van Devender et al. (1992) state that "Hundreds, if not thousands, of isolated, slightly and clearly differentiated populations in woodlands and forests on southwestern mountaintops have *not* been described as subspecies or plant varieties." They then inexplicably leap to the unwarranted conclusion that "Under the Phylogenetic Species Concept (PSC)... where species are defined on the basis of monophyletic lineages, isolated populations with any discernible differences whatever are species ..." Aside from the fact that I did not utilize the PSC (nor the outdated biological species concept) in preparing my list, I would point out that their conclusion is faulty because they neglect to mention that all phylogenetic approaches require allopatric, isolated, montane populations to have fixed, or nearly fixed characteristics (i.e., those that are historically informative) before they would be recognized.

Van Devender et al. (1992) discuss *Crotalus lepidus*, although it is irrelevant to my article because it did not qualify for my list. They correctly point out the tremendous variability exhibited by two races (*klauberi* and *lepidus*) of this snake and indicate this raises the question of whether those two subspecies should be combined (as one race). But again, they inexplicably leap to the unwarranted conclusion that under the ESC the "two variable subspecies of *C. lepidus* would be immediately divided into 20 or 30 species with greater geographic than genetic differences!" Their conclusion is specious, because they again neglect to recognize that I require that taxa show differentiation at an historically informative (fixed, or nearly fixed) level. Obviously, few if any of the "complex mosaic of modestly differentiated populations [of *Crotalus lepidus*] in various habitats, rock types, and elevations" would qualify for recognition at any level. Of more interest is the contention by Van Devender et al. that "most of the populations [of *Crotalus lepidus*] have undoubtedly only been isolated 9000 years or less and *are likely to be reconnected in the future*" (italics are mine). This statement exposes major biases in approach by Van Devender et al., because they assume that most populations of this rattlesnake were connected in the past and will be connected in the future, but they have no evidence to support either assumption. Again, prognostications on the future (and guesses about the past) make for interesting speculation, but are hardly the stuff of objective classifications, and thus are irrelevant. If Van Devender et al. "guess" right, I'm sure that herpetologists of the future will be glad to change their classifications right along with the snakes.

Much of the rest of the paper by Van Devender et al. (1992) discusses various topics—cladistics, phylogenetic systematics, fossil record, biogeography, adaptive responses to geologic events, Pleistocene climates, the age of taxa, evolution through geologic time using as examples numerous taxa that I did not address in my list—but these topics are irrelevant to my list. For example, they state that "subspecies in widespread continental species are more likely to be millions of years old than to have formed in response to the most recent glacial/interglacial climatic cycles," even though they have no hard evidence of this to use in evaluating my list, and even though it has no bearing on classification using the ESC. Actually, it matters not one whit whether a taxon differentiated 10 million years ago or 10,000 years ago; if it is allopatric and diagnosable, it has its own evolutionary fate, and using the ESC, it is a good species. This is a conservative classification, and one that does not brook the abuses of the radical subspecific assignments that occurred during the middle part of this century. Van Devender et al. state that "Barring other information, [*Drymarchon*] *erebennus* could be the living ancestor of [*Drymarchon*] *couperi*." On the contrary, there is no reason to suppose that *couperi* might not be primitive in many ways with respect to *erebennus*—to do so assumes a model of "centrifugal" isolation and differentiation that is hardly supported by historical analyses. But whatever taxon is the presumed nearest living relative, that relationship has no bearing on the specific status of the allopatric *Drymarchon couperi*, any more than between less controversial species pairs like *Bufo retiformis* and *B. debilis*.

Van Devender et al. (1992) state that "The subspecies concept has been very useful in describing patterns of variation within species." I agree that it has been useful in describing variation, but it has also been so abused and twisted over the last 75 years to create so many unnatural relationships in herpetology that it is worthless as a scientific tool and its use is now restricted almost entirely to herpetoculturists who wish to discuss organismal pattern-classes rather than historical entities. Assignment of subspecific names to distinctive allopatric populations is pretty radical taxonomy, at least in an age when a salamander once thought to be a single wide-ranging species can be shown, conservatively, to comprise 13

genetically distinct species (Highton et al. 1989). Van Devender et al. again completely misinterpret the use of the ESC when they state that "*Lampropeltis* would change from a genus with six species with various numbers of subspecies to over 50 species." Even the most casual reading of my article and that of Frost and Hillis (1990) would reveal that the ESC requires much more objectivity and rigor in studies of historical analysis and geographic variation than has ever been applied to that poorly understood genus in the past.

Van Devender et al. (1992) conclude with some statements such as "The new 'species' proposed by Collins reflect a methodology that cannot separate subspecies from species." To the contrary, the ESC can indeed define the difference (Van Devender et al. just don't like the results), and my article reveals a lot of ill-defined subspecies and either replaces them with a list of properly and rigorously defined species, or shows them to be invalid at any level. Put simply, the ESC just defines species differently and conservatively (using evidence instead of assumption). Finally, Van Devender et al. conclude that "a thorough analysis of a taxon with documented evidence should precede any proposed taxonomic change." This statement apparently calls into question the original descriptions of all the taxa on my list. I correctly assumed such an analysis was already done for each of those taxa, otherwise none of them would qualify for recognition at any level. So I encourage readers to not bother with *another* data analysis, just go back and read the original descriptions. If you do so, it will be obvious that you are dealing either with a distinct species or with a population that does not deserve recognition at any level.

Montanucci

Montanucci (1992) states that "the subspecies concept has been abused, that cases of character discordance, polytypic characters, and smooth clinal variation have limited its application . . . and that some subspecies are, in fact, good 'biological' or evolutionary species." Unfortunately, the now outdated biological species concept has nothing to do with the ESC, the latter of which was used to prepare my list of 55 taxa. Thus I reject that linkage by Montanucci, but certainly agree with the rest of his statement. However, he goes on to say that "These variational patterns, in most cases, lend themselves to recognition of geographical subdivisions," and with this I disagree. Some subspecies have been described as the distinctive extremes of clinal variation, but the concept has also been stretched to create such unnatural subspecific assemblages as *Lampropeltis triangulum* (with 25 races from New England to northern South America—this complex actually contains at least four species), *Thamnophis sirtalis* (with 11 races from the Atlantic to the Pacific coasts of North America—this complex contains at least two species), and *Ensatina eschscholtzii* (with 7 distinctive races that badly need re-evaluation). Too often this has been the case, and my list is the opening salvo (at least outside of the journals *Systematic Zoology* and *Cladistics* where this view has been predominant for some time) in an attempt to correct the improper application of the subspecies concept so prevalent during the middle part of this century. The use of subspecies in major herpetological field guides is an historical anomaly that is on the wane (see Collins 1990: Table 3), and very few new subspecies have been described from the United States (only one in the three major English-language herpetological journals in the last quarter of a century). To all this add the elimination of the use of subspecific names in many of the major herpetological preserved collections in this country (e.g., The University of Kansas Museum of Natural History), and it becomes clear that the current unnatural assemblage of subspecies listed in Collins (1990) has fallen into disfavor and is being widely ignored. Montanucci's contention to the contrary, my position is quite tenable. And my list should serve to show how poorly understood the North American herpetofauna is in terms of relationships and geographic variation.

Montanucci (1992) justifies the retention and use of subspecies by referring to them as a common early stage in the speciation process and by implying that using a trinomial calls attention to a distinctive population. This view rests on a particular model of evolution that has been largely replaced. I contend that a large number of the subspecies listed in Collins (1990) would not survive modern analysis. Thus, my recent list (Collins 1991), which was prepared without testing the validity of the subspecies in question, is certain to contain "taxa" that do not merit taxonomic recognition at any level. Indeed, Van Devender et al. (1992) reveal the first of these insignificant variations when they imply that *Lampropeltis pyromelana infralabialis* is only statistically differentiated. Thus, *L. p. infralabialis* obviously does not deserve recognition at any level. These statistically defined populations, when inflated with a trinomial, cause taxonomic distraction and misinterpretation, and undermine the credibility of other taxa that have evolutionary significance.

Montanucci (1992) states that my "proposed taxonomic arrangement is no less arbitrary than the existing taxonomy." That is false. My proposed taxonomy applies a far more rigorous standard to the 55 taxa and at least represents an attempt to be logically consistent with history. After all of the only statistically differentiated variations (that is, where average difference can be discussed without appeal to evolutionary novelties) are exposed and relegated to the synonymy of other populations, my proposed list establishes the most conservative taxonomic arrangement, based on logic and evidence, with none of the assumptions of relationship that resulted in the radical and anomalous taxonomy of the past.

Montanucci (1992) points out that the proximity between the allopatric populations which I elevated to species is variable. I agree, but this has no bearing on their evolutionary fate—it does not matter whether they are separated by 12 inches or 3,000 miles, provided there is no effective gene exchange and they are diagnosable. He also states that the distributional gaps (presumably those shown in Stebbins 1985, and Conant and Collins 1991) may not be real, but until proven otherwise by discovery of new records, that is speculation and has no bearing on the situation. Montanucci also states that distributional boundaries of species are not static, but exceedingly dynamic. I question this for amphibians and reptiles in North America. There have been some spectacular range expansions among North American fishes (e.g., the spread of *Gambusia*), mammals (e.g., the northward migration of armadillos), and birds (the westward expansion of eastern species due to increasing numbers of forests in formerly treeless regions such as the Great Plains), but I know of no comparable examples among our native herpetofauna. Reptiles and amphibians are a comparatively sedentary lot, and I think that most of the distributional gaps in Stebbins (1985) and Conant and Collins (1991) reflect reality, give or take a few miles, and are not an artifact of collecting.

Montanucci (1992) (as do Van Devender et al. 1992) puts forth the arguments that allopatric populations may, through time, come back into contact, and also that the level of morphological distinctness amongst populations is variable. I agree, but both are irrelevant to my proposed list. As stated above, a population is either diagnosable, or it is not. If so, and it is allopatric (or allochronic), it is a species, the most conservative conclusion that can be reached. If not, it does not merit recognition as a subspecies, and I again contend that a number of the subspecies listed in Collins (1990) would not survive investigation, nor would a number of them in my recent list (Collins 1991).

Finally, Montanucci (1992) suggests the herpetological community review my list on a case by case basis, and I find that agreeable, but if they do, it must be by the same criteria that I used in making that list. If a minimal standard of diagnosis and historical independence is applied to each of them, we will see a good number recognized as full species while the remainder will be relegated to synonymy, and the herpetological biodiversity of North America will be clarified. And, seriously, if we are trying to talk about taxic diversity, wouldn't this give us a better measure than the Rube Goldberg classification we have had to put up with for so long? It does not take long and laborious research to evaluate such populations as in my list. The data, if any, are already published in the original descriptions. Historical inertia should not again be allowed to camouflage the amphibian and reptilian diversity of North America.

Summary

The viewpoints of Van Devender et al. (1992) and Montanucci (1992) are based on the outmoded biological species concept and are irrelevant when evaluating my list, because I used the Evolutionary (historical) Species Concept alone to define allopatric populations that had long been held to be morphologically distinct. Because Van Devender et al. (1992) and Montanucci (1992) are wedded to an outmoded concept, they want to keep allopatric, undiagnosable populations as subspecies, but are against specific recognition of allopatric, diagnosable populations that deserve such status. I disagree with them both and reject the biological species concept, and again recommend that the herpetological community adopt my list (Collins 1991). If nothing else, adopting it will set in motion a process whereby the real entities in nature are recognized and those that are inventions will be cast aside.

Species In Contemporary Herpetology: Comments On Phylogenetic Inference And Taxonomy

We thank Robert Hansen, editor of *Herpetological Review*, for allowing us to comment on the criticisms directed at Collins (1991) specifically, and at current systematic theory and practice generally, which appeared in the previous issue of this journal (vol. 23, no. 1). Before responding to specific criticisms we will make some general comments regarding this controversy.

The larger issue in this interchange is not species or subspecies taxonomy; it is that a phylogenetic (= historical) philosophy has replaced the earlier nonhistorical philosophy of systematics. Because the biggest paradigm shift in systematics in the last 140 years has occurred during the last two decades few systematists now defend the philosophy or methods of phenetics or evolutionary systematics. (Note that "evolutionary systematics" is a label for a particular viewpoint that is preoccupied with "biological" species and not evolutionary history.) For philosophical and evidential reasons the clock will not be turned back to the days when classifications were based on overall similarity (either genetic or morphological) or interbreeding (whether actual or potential) rather than on evolutionary (= historical) relationships.

Although a detailed discussion of the "species controversy" is beyond the scope of this reply, it should be noted that the "species problem" persists because it is really several controversies (Kluge 1990: 417). First, there is confusion

between the ontological status (i.e., the *real* nature) of species and how to recognize species practically. While most systematists might be more comfortable formulating diagnoses and dichotomous keys, deciding what they are attempting to discover must logically precede how they search for these items. Second, there is disagreement over the role of species in evolutionary-ecological theory. Some biologists treat species as epiphenomena (e.g., Damuth 1985), while others consider species to be participants *per se* in processes (e.g., Mayr and Ashlock 1991: 26). Third, there is disagreement over the taxonomic treatment of biparental and uniparental organisms. Obviously, the two kinds of organisms cannot be judged in the same way if the criterion of interbreeding is part of the species definition. And fourth, there is confusion over the application of the concept of monophyly to species. Most of Collins' critics make arguments typical of the first controversy, but some of the assumptions they make are related to the second.

The underlying presumption made by several of the critics is that the "biological species concept" (e.g., Mayr 1942) has been, and continues to be, the monolithic view of systematists. However, several of Mayr's own contemporaries (e.g., Blackwelder 1962; Wilson and Brown 1953) found serious problems with the application and underlying philosophy of that particular species definition and it never became popular in botanical or entomological circles. Even in disciplines in which the "biological" species concept did become popular it has been challenged, such as in ornithology (McKitrick and Zink 1988) and herpetology (Frost and Hillis 1990). The primary problem that phylogeneticists have with the concept of "biological species" is that it is not historical (i.e., it is "nondimensional" [Mayr 1942, 1963]) and that classifications based on reproductive compatibility are often inconsistent with the recovered history of evolution. Rosen (1978), Hillis (1988), and McKitrick and Zink (1988) have documented examples of poor correlation of reproductive compatibility with phylogenetic history in fishes, frogs, and birds. The incongruence is thought to be even more widespread in plants (e.g., Grant 1981). As a result of this incongruence and the failure to document that species are direct players in evolutionary processes, most systematists (and other evolutionary biologists) who have followed the controversies have come to the conclusion that the "biological species" of Mayr has no special role in the study of phylogenetic patterns or evolutionary-ecological processes. Also, it has become clear that although systematists can recover the history of evolution with some accuracy, the logical techniques that allow this recovery are unrelated to the existence of potentially interbreeding populations.

Some may argue that reproductive compatibility among allopatric populations is of fundamental interest to evolutionary biologists and that knowledge of the potential to interbreed has improved our understanding of the historical pattern of evolution. However, these advocates must answer what is fundamental about this, and in what pattern or process theories of evolution is *potential* important. Further, what is so fundamental about "species" identified on the basis of *potential* interbreeding that to preserve them we should distort or reject classifications that reflect evolutionary history?

The historically coherent views of species that have supplanted the nonhistorical (= nondimensional) view were discussed recently by Frost and Hillis (1990) and Kluge (1990) so they will not be considered in detail here. What has been generally agreed upon by most phylogeneticists is that species are the largest lineages that lack long-term internal cladistic structure and that species have something analogous to ontogenies, which is organismal character evolution. Further, because there is no particular level of organismal character differentiation or reproductive isolation that is perfectly indicative of the reality or histories of lineages, species can be difficult to discover. Although most phylogeneticists agree that species are lineages, a consensus has not been reached as to how inclusive the recovered entities should be that we hypothesize to be lineages (e.g., compare Donoghue 1985, to Frost and Hillis 1990, and Kluge 1990). In practice, however, entities considered to be species in a phylogenetic context are often smaller than hypothesized "biological" species. However, contrary to the apocalyptic visions of some (e.g., Van Devender et al. 1992), the application of phylogenetic philosophy and methods has not resulted in the unrestrained naming of all allopatric populations.

Although "biological" species are defined on the basis of reproductive compatibility, the reality of lineages does not turn on the basis of allopatry, diagnostic features, intrinsic reproductive closure, or the presence of humans to delimit them. Species are real entities rather than convenience constructions, so there seems to be no way to avoid their inherent slipperiness. That is, there is no way to avoid the inherent difficulty of analyzing real data. Because intrinsic reproductive closure is the rule for identifying "biological" species, it might seem useful to have analogous standards for recognizing lineages as binominals (Highton 1989, or Smith 1990). However, there is no reason to assume that we should be able to recover all lineages, so any recognition rule would necessarily be arrived at by pact rather than by discovery.

However, it should be difficult to retrieve historical patterns below the level of species (bisexual) (except for clonally inherited portions of the genome such as mitochondrial DNA) because we *expect* historical reticulation of populations below that level. We know that as the species level is approached evidence for distinguishing lineages becomes more ambiguous (Arnold 1981), particularly when dealing with such kinds of data as allozyme frequencies (see Crother 1990, and Gaines et al. 1978). Therefore, even when confronted with a plethora of statistically identifiable local populations, the lack of recoverable historical structure among them indicates to most phylogeneticists that the level of species has been reached. However, even if we do occasionally slip below the level at which we are aiming (i.e., if the populations that we mistakenly call species will reconnect and genetically swamp each other in the future), this might give us additional information about the history of evolution, which is really our primary objective. Even so, errors of species identification are not limited to attempts to discern lineages, and, indeed, also seem characteristic of the search for "biological" species.

Regardless of continuing philosophical and operational controversies, the action of Collins in recognizing as species the allopatric, differentiated (at least enough that previous taxonomists thought they were recognizable) populations of amphibians and reptiles in the United States is in step with most recent discussion of species (e.g., de Queiroz and Donoghue 1988; Eldredge 1985; Eldredge and Cracraft 1980; Frost and Hillis 1990; Kluge 1990; Wiley 1978, 1980). Although we have some misgivings about promoting taxonomic innovation not based on specific discussion of evi-

dence, we feel strongly that the time has arrived to move away from nonhistorical (= nonevolutionary) classifications and toward classifications that reflect what we can recover of evolutionary history. That a translation from a nonhistorical to a historical taxonomy cannot be made totally without error is little reason to avoid the change. There is no special revealed truth in traditional taxonomy and there are good reasons to think that traditional practices can hinder progress. Also, we do ourselves little good in continuing to base classifications on predictions of the future of evolution (i.e., that differentiated populations will reconnect). Regardless of our ability to reconstruct the pasts of lineages, we can never know their futures. Only where laws of nature apply is it reasonable to make such kinds of predictions.

The issue of "subspecies" is not whether they are useful as "pattern classes" for the vague generalities of casual discussion, but whether subspecies are discoverable items (i.e., temporarily isolated sublineages) or invented (in which case they are simply artifacts of idealizing diagnoses to fit our notions of process). If they are discoverable, then they clearly are elements of evolutionary biology; if they are invented they are an impediment to the formulation of historical hypotheses. Within the historical context of phylogenetic inference the use of subspecies (= *temporarily* isolated sublineages; *not* "incipient" lineages) is severely restricted. This is because identifying a sublineage requires the same kind of evidence for recognizing a lineage, not less, and also requires the additional assumption that the sublineages will reconnect in the future to reconstitute the lineage. That is, not only does one have to supply evidence that the sublineage in some diagnostic sense is "apart," one must supply evidence of its phylogenetic closeness to some other sublineage, and provide evidence that they will become confluent in the future (i.e., that they are really subunits of some larger evolving lineage and not lineages themselves). As mentioned previously, no theoretical justification exists for such predictions. Nevertheless, even within traditional practice the use of subspecies is problematic. When considering the papers by Collins' critics and their views on traditional subspecies application, bear in mind the following quotations from Mayr (1982):

> "Hence, it became clear that the subspecies was not a concept of evolutionary biology but simply a handle of convenience for the clerical work of the museum curator. The subspecies was likewise found deficient when studied as the adaptive response to local environmental conditions. During the study of clines, workers found the more-or-less arbitrarily determined subspecies borders to be often more of a hindrance than a help . . ." (p. 594).
>
> "Today, however, the primary use of subspecies is as a sorting device in collections, that is as an index to populations that differ from each other 'taxonomically.'" (p. 595).

By "taxonomically" Mayr meant that "subspecies" designation is heuristic and refers both to items that are discovered (elements of evolutionary biology; entities we would consider to be evolutionary species) or invented (not elements of evolutionary biology; items excluded from historical classifications). Based on our collective experience of curating large herpetological collections, we have found only two clerical uses for the subspecies category, both of arguable value: (1) trinominals (particularly those representing diagnosable allopatric or parapatric populations) often turn out to be species under any popular definition of that term, so it is frequently easier to retain preexisting trinominals on jar labels than reidentify and rebottle specimens when taxonomic revisions are made; and (2) trinominals can allow us to set aside controversies over whether one or two species are involved within some binominals. However, particularly for North American taxa, subspecies designations more frequently make for curatorial hassles, technician make-work, and misinformation for uncritical collection users. For these reasons many collections have either abandoned the use of trinominals or severely restrict their use (e.g., American Museum of Natural History, Natural History Museum of Los Angeles County, University of Arizona, University of Kansas, and University of Michigan).

Secondarily, having trinominals do double-duty in traditional taxonomy has been detrimental to communication and therefore science. They have been used to aggregate evolutionarily independent lineages into one binominal on the basis of inferred potential to interbreed and they have been used as nonhistorical geographically continuous convenience classes so that morphological generalities could be idealized (the trinominal usually illustrating one or two geographically variable features at the cost of ignoring other geographically incongruent trends). The possibility of any scientific generalizations about "subspecies" is precluded by this confusion of definitions. For example, in the current subspecific taxonomy of *Crotaphytus* (Axtell and Montanucci 1977; Ingram and Tanner 1971; Montanucci et al. 1975; Sanborn and Loomis 1979; Smith and Tanner 1972) the mixture of evolutionary species (*bicinctores* [variably considered a binominal], *vestigium, insularis,* and likely *nebrius*) with convenience inventions (*auriceps, baileyi, collaris,* and *fuscus*) renders the scientific utility of these trinominals minimal without specific information about particular taxa. Note that if "subspecies" in the "biological species" sense really had anything to do with that concept of species, taxonomists trying to apply the concept of "biological" species would require that subspecies be recognized on the basis of developing reproductive incompatibility, i.e., that the populations designated "subspecies" were demonstrably undergoing "speciation." One hears the claim that "subspecies" (particularly allopatric ones) are incipient "biological" species (e.g., Mayr 1982), but the data to support this notion (i.e., demonstration of partial reproductive isolation) are rarely produced, largely because in traditional taxonomic practice morphological differentiation and the development of intrinsic reproductive isolation are frequently conflated (Larson 1989). Traditional subspecies recognition rests on notions that are unrelated to the biological species concept. That is, the "multidimensional" species concept (the operational aspect of the "biological" species concept wherein potential "biological" species are divined on the basis of overall similarity) really is an uncomfortable mixture of the "nondimensional" species concept (the theoretical aspect of the "biological species concept") with pre-1940's taxonomic practice. Even if one thought that "biological species" were acceptable and useful, it would seem that fifty years after the formulation of the notion of "nondimensional" species it would be time to jettison a notion of "subspecies" that is unrelated to the development of intrinsic reproductive closure, the only measure of "biological" species.

So, for the reasons discussed above, we think that Collins' paper is just the stimulus that herpetologists need to take up seriously the issues of species discovery, phylogenetic infer-

ence, and the development of classifications that are logically consistent with recovered history. With respect to the social inertia that Collins' note has uncovered, we are less dismayed that so many herpetologists would use and promote the use of subspecies than we are that they would concomitantly object when these nominal taxa are expected to measure up to being elements of evolutionary biology.

Collins' use of allopatric distribution and morphological distinctness may be criticized because those data are not as refined as we might like. However, they do constitute evidence, and to ignore such is to be nonscientific. Collins has merely noted those allopatric populations that previous taxonomists have regarded as distinctive enough to warrant names and taken that as evidence that the populations are on unique phylogenetic trajectories. If workers have disagreements with the published evidence (e.g., with the diagnoses supporting the distinction of allopatric populations and the concomitant hypotheses of their ontological status) then they should publish corrections, regardless of the rank of the taxon. However, although the older "polytypic" species classifications have tradition on their side, most recent studies (e.g., Highton 1989, on *Plethodon;* or Platz 1989, on *Pseudacris*) suggest that species, even "biological" species, are generally considerably smaller geographically and less variable than once supposed. Moreover, it is rare that evidence has been presented to support the historical propinquity of allopatric subspecies. So, tradition aside, it seems that we would be better served by scientifically more conservative classifications (i.e., ones making fewer claims of relationship) than those in general use now.

We agree that the wholesale recognition of allopatric but occasionally erroneously diagnosed populations will cause some nominal taxa that have either ambiguous or no evidential support to be recognized as binominals. We find it revealing that most trinominals appear to have been accepted uncritically and used broadly, and only the hypothesis that many are species has elicited any recent scientific interest in them. This change in Linnaean rank, however, does not change the fact that these nominal *taxa* are no more problematical now than they were as nominal subspecies. Collins' paper may have missed the mark with respect to a number of particulars (e.g., in the unexplained [and spotty] retention of apparently arbitrary subspecies in some binominals such as *Rana capito* and in the omission of some well-differentiated species such as in *Uma*), but he merely applied existing evidence to a field that has otherwise been stultified by tradition and a desire for stability even when this might promote misinformation about evolutionary history.

Unfortunately, phylogenetics (= cladistics) and its underlying philosophy are not accurately portrayed by Collins' critics, particularly by Van Devender et al. (1992). Because it is the basis for most recent systematic work and for the current revolution in evolutionary-ecological biology (Brooks and McLennan 1991), herpetologists would be well advised to become familiar with phylogenetic inference. To do so will obviate almost all of the concerns addressed by these authors.

Replies To Individual Critics

Reply to Grobman (1992).—We think that Grobman's (1984) erection of a number of arbitrarily delimited "subspecies" of *Opheodrys aestivus* has been largely ignored by the herpetological community for sound reasons. Although we encourage the study of geographic variation as a vehicle for discovering historical entities, Grobman's infraspecific taxonomy of *Opheodrys aestivus* is illustrative only of the arbitrary delimitation of nonhistorical taxa and the moribund 75% rule of subspecies distinction. Activities of fundamentally different kinds, invention and discovery, are not distinguished by Grobman in his infraspecific taxonomy. Indeed, Grobman never suggested that his defined races were (or had been) historically independent entities at all, and certainly not subspecies in any *historical* use of the term. Therefore, because his taxonomy does not tell us about historical lineages, his trinominals are clearly not elements of evolutionary biology. Grobman's raw data might have helped discern historical entities, but unfortunately those data were presented in such a way as to presuppose the existence of his nominal subspecies, with no formal discussion of the broadness or narrowness of intergrade zones, no detailed documentation of species-wide geographical trends or homogeneity of populations, nor any discussion of what the patterns he discovered might mean historically.

That Collins (1990) and Conant and Collins (1991) did not include these nominal subspecies but did include other arbitrary races (e.g., several in *Coluber constrictor* and *Lampropeltis getula*) does not mean that they should have included Grobman's nominal races. It means that there still are many other arbitrarily delimited races that need to be addressed by taxonomists and removed from field guides. Further, field guides and checklists, as useful as they are, are not arbiters of anything, and, more often than not, merely reflect the social conservatism of the community rather than the *evidential* conservatism of scientific inquiry. That systematists generally have not accepted Grobman's trinominals reflects that they represent a taxonomic tradition that has been discarded, even by most nontheoretical systematists.

Reply to Lazell (1992).—We agree with Lazell that herpetologists, like other biologists, must become informed about what the species controversy is, and judge for themselves the merits of each taxonomic change suggested, rather than just blindly accept all proposals. However, Lazell should know that acceptance of taxonomic novelty rests on published evidence and philosophical argumentation rather than on the popularity of the animals. For instance, his repeated assertion that *Thamnophis* is a synonym of *Natrix* (Lazell 1972, 1976, 1989a, b) has not been accepted because the preponderance of evidence (Lawson 1986; McDowell 1961; Rossman and Eberle 1977) shows that at least eight other genera of snakes (including *Storeria,* which Lazell 1989b, retains as distinct) are more closely related to *Thamnophis* than is *Natrix*. Similarly, there has been no acceptance of his contention that *Brachylophus* is a synonym of *Iguana* (Lazell 1973, 1989c) because the preponderance of the evidence shows that there are five other genera of iguanid lizards (including *Sauromalus* [chuckwallas] and *Amblyrhynchus* [marine iguanas]) that are more closely related to *Iguana* than is *Brachylophus* (de Queiroz 1987; Norell and de Queiroz 1991).

We agree with Lazell that considerable work remains to be done to retrieve the historical patterns among taxa of amphibians and reptiles, and that any classification suggested is only as good as the evidence that has been presented to support it. Where we seem to disagree is over whether much of the taxonomy for polytypic amphibians and reptiles has much in the way of critical support, or whether it has just been anointed by tradition.

Response to Montanucci (1992).—Although Montanucci says that he is a strong supporter of the evolutionary species concept, he retains the traditional "biological" concept of "speciation" and wants to retain the use of nominal subspecies because of their purported heuristic value. His position appears identical to that of Mayr (1982) and Mayr and Ashlock (1991), who are not supporters of the lineage species concept. Our objections to this approach are taken up earlier in this paper and in those previously published (Frost and Hillis 1990; Kluge 1990).

We do not understand the reason for Montanucci's appeal to tradition (the widespread use of subspecies in field guides and other literature) to support the use of trinominals. This has nothing to do with scientific discourse. We do not agree with Montanucci's assertion that Collins did not provide evidence for the previous paradigm being outmoded. We suggest that his literature citation to Frost and Hillis (1990) accomplished that. Contrary to Montanucci's statement that use of "subspecies" is a practice that continues to be well thought of, he will have to explain why the naming of subspecies has become so uncommon relative to practice twenty years ago. Neither do we accept his assertion of the overriding utility of trinominals, which is obviated not only by evidential limitations but by definitional ambiguity (see our earlier discussion and example of *Crotaphytus* taxonomy). Additionally, Montanucci's citation of Wiley's (1981) models of speciation in support of subspecies is spurious; Wiley specifically abjured the "biological" species concept and its attendant subspecies concept, and he still does (E. O. Wiley, pers. comm.).

Although we agree with Montanucci that the evidence for the recognition of the binominals recognized by Collins varies (although we think that Montanucci's number of 32-38 being undiagnosable is too high), the reality of lineages does not depend on any particular level of organismal differentiation. We worry that Montanucci is confounding a notion of "lineageness" with organismal morphological distinctiveness, much as morphological divergence has been confounded with the development of intrinsic reproductive closure by many traditional taxonomists (Larson 1989). Montanucci does not seem to be bothered that this "problem" is also evident among many "biological" species and certainly among traditional "subspecies." Of course, we too would be hesitant to recognize taxa on the basis of poorly sampled populational variation (at least when and where adequate sampling is possible). However, that allopatric subspecies have been recognized as distinctive enough to be named by earlier authors certainly renders these as hypothesized lineages, i.e., species. As hypotheses they are open to continued investigation and acceptance or rejection, just like hypotheses of allopatry. If a taxon is not diagnosable, it should have never been recognized as a subspecies, much less a species.

We agree with Montanucci that, in some better world where evidence and hypotheses are continually reinvestigated and tradition has no role in science, we would want to wait for the problems that Collins has uncovered to be dealt with on a case by case basis. However, we see little evidence that herpetologists were aware that these are problems that need to be tackled.

Reply to Van Devender, Lowe, McCrystal, and Lawler (1992).—These authors misunderstand or misrepresent much of what has been written on the topics of species and phylogenetic inference. Additionally, they make several unwarranted assumptions about the evolutionary process as well as unsupported claims—largely on the basis of "unpublished data"—about the plethora of binominals that would be recognized under a historically coherent view of species.

The paramount confusion that we detect in these critics' views is between (1) what species are, and (2) how these are identified. The identification and ranking rule of "actually or potentially interbreeding populations" (the biological species concept) does not tell us that polytypic species composed of allopatric subspecies are evolutionary entities. It merely says that the constituent subspecies share a characteristic (reproductive compatibility) that logically must be a primitive feature, and is therefore uninformative phylogenetically. That is, there is no necessary relation between Van Devender et al.'s definition of "conspecific" and their definition of "relationship" (which they consider synonymous with "genetic similarity"—see below). Even though Van Devender et al. have levelled the accusation (pp. 10-11) that species have been redefined as lineages to make life easier for phylogeneticists, the issue is not ease of application; it is whether we should make exceptions to a taxonomy designed to reflect evolutionary history in order to preserve "potential" entities and traditional notions about "kinds" of organisms.

With respect to these authors equating "relationship" with genetic similarity (p. 12) rather than evolutionary (= historical) relationship, there is considerable evidence that their definition of relationship is incompatible with some of their other beliefs. Genetic similarity and "speciation" (by their definition, development of intrinsic isolating mechanisms) are poorly correlated in many cases, such as is demonstrated by the observation that some Mexican populations of *Ambystoma tigrinum* are genetically more similar to *A. dumerilii* (a morphologically and reproductively distinctive species) than to some other Mexican populations of *A. tigrinum* (Shaffer 1984). Moreover, it seems incautious for Van Devender et al. to presume that assessing a few morphological characteristics (some of which, like ventral and subcaudal counts, can show strong epigenetic effects) is a good way to measure genetic similarity.

Van Devender et al. (pp. 11-12) supply a number of examples where phylogeneticists, if they were privy to unpublished data, would be forced to arrive at taxonomic conclusions that Van Devender et al. consider unacceptable. Their statements aside, we would have to evaluate their data to see if any historical structure were recoverable and/or the populations of snakes that they address met some evidentially unambiguous level of diagnosis before we would agree with their undocumented assertion that recognition of many species is consistent with the data. It would be interesting if they could rigorously diagnose the different populations of *Crotalus lepidus* in Texas without appeal to frequency data or casual discordant trends. More informative would be any historical patterns that might be discovered. We would have hoped that as biologists interested in the history and biogeography of southwestern North America that this would have been their primary preoccupation, rather than maintaining traditional practices that impede recovering evolutionary history. Ironically, Van Devender et al. criticize phylogeneticists (p. 13) for using "fixed" characteristics for taxon recognition (see below) and then apparently assume that phylogeneticists would use some lesser evidential requirement in order to validate their apocalyptic vision of the "breakup" of *Crotalus lepidus*.

The discussion of *Lampropeltis mexicana* group taxonomy

shows an unwillingness of Van Devender et al. to follow their own underlying philosophy when it requires the taxonomic "lumping" of well-marked species. It is well-known in herpetoculture circles that crossing of *L. triangulum*-group taxa with other *Lampropeltis* "tricolors" requires behavioral manipulation to overcome premating isolating mechanisms. However, it is also well-known that such premating isolating mechanisms (or postmating isolating mechanisms) are either poorly developed and insufficient ("incipient") or do not exist between *L. alterna, L. mexicana, L. pyromelana, L. ruthveni,* and *L. zonata* (Garstka 1982; Frank Retes and Ernie Wagner, pers. comm.). It has been argued that captive breeding is not a legitimate means of testing for the presence of pre- or postmating isolating mechanisms. However, wholesale rejection of data from captive breeding renders hollow the claim that potential to interbreed is the touchstone of species-level taxonomy. Inasmuch as Van Devender et al. use evidence from captive breeding (Garstka 1982; and reporting that *L. alterna* breeds freely in captivity with *L. mexicana*) to support their taxonomic views, they should not stop with synonymizing *L. alterna* with *L. mexicana*; they should consider *L. alterna, L. mexicana, L. pyromelana, L. ruthveni,* and *L. zonata* to be representatives of a more extensive *L. zonata*.

The listing by Van Devender et al. of particular subspecies with associated biomes is illustrative of an approach to phylogenetic inference and biogeography that we reject as lacking rigor. To cite some examples (and using their classification), the characterization of *Lampropeltis g. splendida* as a Great Plains form is obviated by the central Great Plains distribution of *L. getula* being an intergrade zone between *L. g. splendida* and *L. g. holbrooki* (*L. g. nigrita, L. g. splendida, L. g. holbrooki,* and *L. g. nigra* likely intergrading insensibly for the entire length of their combined distributions [data from Blaney 1977]). Another subspecies that they characterize as being a Great Plains race, *Lampropeltis triangulum gentilis,* does not overlap "pure" *L. getula splendida,* but only the *L. g. splendida X L. g. holbrooki* "intergrade" zone, and when the distribution of another of their Great Plains subspecies, *Crotalus v. viridis,* is taken into account, it becomes unclear what the geographic and evolutionary commonalities are that Van Devender et al. think are so obvious. The presence of only one of these "subspecies" (*L. t. gentilis*) is limited to the Great Plains so it seems that the generalities about geography and "adaptive response" made by Van Devender et al. are as imprecise as their systematic generalities. Van Devender et al. imply that the underlying cause of the evolution of these nominal subspecies is the "Great Plains." Would not their implied hypothesis of the evolution of these "subspecies" be more compelling if the "entities" hypothesized to have had a shared cause of origin had congruent distributions and congruent phylogenies? In fact, would not it be best if the "entities" that they were discussing were actually entities, rather than convenience inventions? In effect, they run into the same problem as do those who want to treat nominal biomes as if they were entities, rather than convenience inventions. In this vein, what does "mainland Mexico Sonoran Desert" mean ecologically and "adaptively" with respect to *Masticophis flagellum cingulum* (an arbitrarily defined pattern class [data from Wilson 1970] which is found from lower Sonoran desert to mesquite desert-grassland to Sinaloan thornscrub)? The characterization of *Crotalus viridis cerberus* as a "Mediterranean chaparral" element ignores the wide distribution of this snake in the Transition and Canadian Zones of Arizona (Lowe et al. 1986). Additionally, we find the implied hypothesis of a Miocene origin (8-20 million years ago) (p. 12) of many Southwestern subspecies surprising in light of the implication by Van Devender et al. that species usually are readily identifiable (i.e., "usually distinctive"). Few reptiles from the North American midcontinental Miocene can be identified with any certainty to Recent species (much less subspecies), and frequently not beyond genus (Estes 1983; Robinson and Van Devender 1973).

Van Devender et al. claim (p. 13) that phylogenetics cannot separate species from subspecies. Of course, this assertion rests on their definitions of speciation, species, and subspecies, so they may be correct. However, inasmuch as they have not provided evidence supporting the hypothesis of incipient intrinsic reproductive isolation of any of their "subspecies" or distinguished between convenience inventions (arbitrary "subspecies") and lineages, we suggest that *their* approach is deficient. Proponents of "biological" species are on *very* shaky ground if they attempt to claim ease of application for their particular concept (Ehrlich 1961).

The repeated assertion by Van Devender et al. that under a phylogenetic world view "species" can revert to "subspecies" reveals their misunderstanding of the nature of evidence, their confusion between the entities to be discovered (lineages) and the species rank in the Linnaean hierarchy, and their failure to distinguish between discovery and invention. Yes, the evidential basis for discovering species (or any taxon) is *necessarily* faulty. Mistakes are made, and with additional evidence (published) we revise our conclusions. This is hardly radical and, instead, is a central characteristic of all scientific inference.

Van Devender et al. evidence several beliefs that extend beyond or are contrary to evidence. They state (p. 10) "the allopatric populations of Collins (1991) are, *of course* [italics ours], potential interbreeding populations." What data do they have to support this blanket assertion? They repeatedly claim that ancestor-descendant relationships among living species are more common than paired sister-taxa. Beyond our theoretical disagreement with this statement, they present no evidence that would support the notion that relatively completely primitive "ancestors" are more common than sister-species (or that they are common at all); it has not been supported by the study of *Coleonyx* (Grismer 1988; Kluge 1975), pygopodids (Kluge 1976), or leopard frogs (Hillis 1988). The implied commonness of "speciation" by peripheral isolation also does not seem to be predominant. In the only phylogenetically controlled study known to us, Lynch (1989) found that among 66 cases of species pairs in fish, frogs, and birds, 71% were explained by more-or-less equal vicariance and only 15% were explained by peripheral isolation. Van Devender et al.'s statement (p. 12), "An ancestor and its descendant will always have a greater genetic similarity and fewer character changes than paired descendants of the same ancestor," is another unsupported claim made for no discernible reason. Their assertion (p. 12) that "the temporal coexistence of ancestral species or subspecies in older habitats with their descendants in derived habitats is the normal state of affairs" rests not on data, but on unsupported notions of evolutionary process and a belief that biomes are integrated evolutionary entities rather than convenience inventions. Additionally, in light of the stability and antiquity of subspecies (see above) claimed by Van Devender et al. (and using their taxonomy), why is it necessary for them to posit that

"stabilizing selection is very strong" to explain why *Lampropeltis pyromelana infralabialis* is similar to *L. p. pyromelana*, which they claim is only 10,000 years separated from *L. p. infralabialis*? What body of data supports their assertions of particular selection regimes on their other examples of *Coluber* and *Drymarchon* populations? From these examples and others in their text it is clear (regardless of the discussion of Miocene orogenies and Pleistocene climates and biotic communities in the southwestern United States) that Van Devender et al. are not supporting their preferred taxonomy on recovered history, but on assertions about the future of populational interactions and unwarranted (or wrong) presumptions about the evolutionary process.

Van Devender et al.'s statement (p. 11) that—"Reticulate evolution, a common evolutionary mechanism in plants, has occurred in many animal populations currently recognized as subspecies. Cladistics cannot reconstruct the phylogeny of groups with reticulate evolution"—disregards or misrepresents the literature and evidence. Although we have noted (see above) that we cannot recover histories of populations once reticulation has obscured the trail, with regard to "subspecies" (sense of Van Devender et al.) we know of none for which data support a reticulate origin rather than vicariance (or arbitrary christening) so we do not know how Van Devender et al. could have reached their conclusion. Those working on taxa of hybrid origin are not dealing with "subspecies" in the sense of Van Devender et al. But, with respect to reticulate evolution among lineages, there are data (e.g., hybrid karyotypes) that can allow detection and several phylogeneticists (including several botanists) seem to deal happily with the phenomenon in their taxonomic work (e.g., Bremer and Wanntorp 1979; Buth 1984; Funk 1981, 1985). Those working on parthenogenetic lizards derived from hybrid origins (e.g., Wright and Lowe 1967) have certainly applied the rule of evidence to the problem to good effect. Regardless, how can reticulate evolution be studied or even identified except within the context of a covering phylogenetic hypothesis? Apparently Van Devender et al. have mistakenly tried to restrict phylogenetics to the construction of dichotomous cladograms. But, cladistics is about rigorous methods of inferring the history of evolution, the rule of evidence (not just morphological evidence as asserted by Van Devender et al. on p. 10), and minimizing assumptions about how evolution proceeds. Compare this with the casual scenarios and unsupported assertions offered by Van Devender et al.

Finally, because this seems to be the real objective of their criticisms, Van Devender et al. summarize the putative logical errors of phylogenetics (= cladistics) in four points (p. 12), which we quote:

1. "All characters are equally important and potentially species characters." Contrary to Van Devender et al.'s opinion, we do not claim that there are "species characters"; we merely claim that all organismal characters may provide evidence of the history and existence of taxa. Although Van Devender et al. imply that there is only one "species character," which is intrinsic reproductive closure, they also seem to believe that there are differences in the relative importance of characters to particular taxonomic levels. If species are real things rather than just a rank in the Linnaean hierarchy there is nothing that could support this assertion.

The related claim by Van Devender et al. (p. 13) that phylogenetic techniques taken to discover species render the recovered entities typological is palpably wrong. In typology, membership in *invented* sets (nominal taxa) extends from the definition used for set identification regardless of tokogenetic (= interorganismal) relationships; there is no concern for discovering real entities. In phylogenetics, we attempt to discover entities which are difficult to apprehend and because of this the techniques that we use are conservative. Because of the inherent difficulty of evidence near the level of species, the tendency among phylogeneticists is to use "fixed" (= *very* widespread) characteristics in analysis (although "fixation" is clearly a methodological fiction). If anything, accepting the arbitrary delimitation of insensibly intergrading subspecies is much closer to the original tradition of typology than anything going on in modern systematics.

2. "The degree of genetic similarity or divergence is irrelevant." As stated before, we agree with this statement inasmuch as we are not asking questions about similarity or divergence—we are asking questions about history.

3. "Most ancestors [= ancestral species] are assumed to become extinct at the time of speciation." No one, to our knowledge, has ever made the claim that *most* species go extinct at speciation, but the issue that Van Devender et al. obviously are trying to get at is that many phylogeneticists take the position that *all* branching points in a phylogenetic tree constitute lineage originations (= speciations). This is hardly a fundamental principle of phylogenetics, as evidenced by well-known cladists who have not taken this position (e.g., Brooks and Wiley 1986; Wiley 1981). Nevertheless, we do accept it. To do otherwise requires taxonomy to rest on the subjective evaluation of organismal similarity rather than on evolutionary history. See the following point.

4. "The most closely related species are paired descendants sharing their ancestor's derived characters." This point rests on the definitions of relationship and species that Van Devender et al. think are applicable. Nevertheless, lineages are not hydras or humans (i.e., they are not what philosophers refer to as interactors or replicators) so to talk about "ancestry" of one lineage to another requires appeal to a subjective measure of organismal similarity rather than appeal to the evolutionary history of lineages. The analogy of organismal reproduction to lineage origination is not gestation and birth; it is mitosis or schizogyny. The ancestral lineage, once divided, must be taken to be *all* of its descendant lineages, not just the lineage among them with the most conservative organismal diagnosis. However, this and the previous issue have no impact on the recognition of extant species, so in this context they are red herrings.

In conclusion, we urge Van Devender, Lowe, McCrystal, and Lawler, biologists who clearly are interested in evolutionary history, to not let their notions of evolutionary process overwhelm their analyses of evolutionary pattern. We also invite these authors to publish the data on which so many of their assertions and examples rest so that the community can evaluate their claims.

Acknowledgments.—For helpful criticisms (not necessarily agreement) on various drafts of this paper we thank Paul Chippindale, Kevin de Queiroz, Maureen Donnelly, Lynne Frost, Gina Gould, Michael Klemens, Roy W. McDiarmid, and Charles W. Myers.

TECHNIQUES

An Efficient Marking Technique For Softshelled Turtles

Ferner (1979) and Plummer (1979) summarized conventional marking techniques for freshwater turtles and discussed criteria for marking and tagging. Ernst et al. (1974) reviewed marking techniques and proposed a coding system for capture/recapture studies of hardshelled turtles. The marking of softshelled turtles (*Apalone*: Trionychidae) was first described by Breckenridge (1955). Breckenridge utilized several techniques (including "bolt tagging," leather punching, and Woodbury's [1948] ink tattooing) with varying degrees of success, and concluded that "notching" of the periphery of the shell was the only satisfactory method. Breckenridge (1955) noted that the notches healed readily but remained discernable for up to five years. Plummer (1977) noted that triangular notches carved into the edge of the shell of *Apalone mutica* healed within a year but left distinct scars.

Edge notching, however, may be obscured in older specimens as the periphery of the carapace can become frayed or damaged with age, and regeneration can quickly obscure notch scars in juveniles. In addition, we have found 28 specimens of *Apalone spinifera* and 24 specimens of *Apalone mutica* which displayed bite scars near the edge of the carapace that resembled the scars left by shell notching. These individuals were from shallow water localities with high softshell densities. We attribute these "bite" scars to aggressive behavior which may be related to high population densities. These scars have been observed in comparable frequencies both during and out of reproductive season, so they do not appear to be related to breeding behavior. Aggressive biting may be a factor which serves to regulate population density or promote dispersal in the water system.

The following is a technique, refined from Breckenridge (1955) and Plummer (1979), which is an efficient, effective, and convenient method for positive identification of individual softshells. This technique satisfies the marking criteria of Ferner (1979) and Plummer (1979), minimizes time and effort for the investigator while maximizing the number of turtles marked, requires little equipment, appears to demonstrate a low loss of marks, and eliminates confusion due to bite scars.

A standard, office supply, handheld paper hole punch (hole diam = 4 mm), may be used to mark the periphery of the carapace, preferably in patterns which yield the most scientific information, such as the coding proposed by Cagle (1939). Holes punched through the carapace are clean, uniform, and provide numerous possible combinations of patterns. The marking leaves little, if any, bleeding and the turtle shows very little reaction to being marked. It is recommended that the holes be made at least 5 mm from the edge of the carapace to ensure that the hole retains its integrity and leaves a recognizable scar.

This method is superior to edge notching (usually accomplished with a knife blade) and marks made with a leather punch due to the following: it is accomplished more quickly and with less chance of damage to either the turtle or the investigator; it eliminates the potential for misidentification due to bite scars or shell fraying; it completely removes all of the tissue, whereas leather punches leave a hinged, uncut portion of the shell.

Punched holes also provide a suitable tie-off for wire or line which may be attached to a tracking balloon. Plummer (1979) and the authors found balloon tracking to be useful for short term observations. In these cases, distance of the hole to the edge of the carapace should be minimized to facilitate escape if the animal becomes entangled by the wire. Even minimal pressure on the line will pull it through the edge of the carapace, preventing entrapment and drowning.

This technique has been successfully utilized for four years (1988-1992) in mark-recapture studies of *Apalone spinifera* and *Apalone mutica* in Louisiana. One hundred thirty-seven individuals of the two species were marked in the above manner and recapture rates were recorded. Of 137 individuals, 10 have been recaptured; of these, 2 have been recaptured 3 times. The recaptures occurred between 10 and 706 days after the initial marking. The hole showed signs of healing at 10 days, and was 30% – 70% healed in animals recaptured at 23, 36, and 39 (n = 3) days. The hole was completely healed (filled in and showing scar tissue) within a minimum of 70 days and was discernable in animals recaptured at 306, 345, 399, 403, and 706 days. The scar is most visible on the ventral surface and can be remarked at recapture, if desired. The scar appears as an area of lighter color than the surrounding tissue and the periphery of the original hole is marked with minute surface striations.

Acknowledgments.—We thank R. A. Seigel and M. V. Plummer for their comments and encouragement.

An Efficient Method For Measuring Salamanders

Many experimental protocols involving salamanders require accurate morphometric measurements of living animals. Measuring salamanders can be problematic because of their slimy skins and sinuous movements, especially if these measurements must be obtained in the field. Several techniques have been described previously for standard measurements, such as snout-vent length, tail length, total length, and head width. For example, the red-backed salamander, *Plethodon cinereus*, has been measured in several ways. Taub (1961) measured a salamander by placing it on a white paper card, prodding it to move into a straightened posture, and marking with a pencil the snout, tip of tail, and an "estimated" position of the vent. Mathis (1991) placed a salamander in a clear graduated (in millimeters) plastic tube (110 mm length, 0.9 mm diam). Fraser (1980) described a technique for detecting and measuring oocytes (visible through the abdominal wall) by placing a salamander on a piece of glass. Hairston (1980) measured other species of plethodontid salamanders by placing them on a piece of glass and restraining them with a towel. The problems with these techniques are (1) when the salamander is forced to stay still (i.e., is restrained) as in a tube, under a towel, or on a piece of paper, it tends to contort its body, making precise measurements difficult, and (2) when the salamander is allowed to move freely across a substrate (e.g., a piece of paper) such that the body may straighten, measurements must be made rapidly or must be estimated before the salamander changes position.

The keys to the precise and accurate measurement of salamanders are (1) to allow the salamander to assume a body position such that the vertebral column is straight along its complete length and (2) to maintain the salamander in this straightened position for a period of time that is adequate to obtain the desired measurements. Animals could be anesthetized to achieve accurate measurements; however, for many behavioral tests and ecological studies, it is preferable to avoid anesthesia because of the possibility of altering the behavior of the test animals (Buchanan and Jaeger, in press) and because anesthetization can be time-consuming and difficult to employ in the field.

As an alternative to anesthesia, we describe an accurate and efficient measuring device for obtaining morphometric measurements of salamanders in the laboratory or in the field. This device (the "mander masher") has been used successfully to measure species of plethodontid salamanders including adults and juveniles of *P. cinereus* and *P. glutinosus*, but sizes and materials can be altered for the measurement of other salamanders as well.

The design includes a transparent cover plate (21 x 13 cm piece of 2.5 mm thick Plexiglass), base plate (23 x 13 cm sheet of 1.5 mm thick aluminum), sponge with small pores (20 x 11 cm, 1.5 cm thick), two hinges, and two stop bolts (nuts and bolts) (Fig. 1). The transparent Plexiglass cover plate is attached, using hinges, to the aluminum base plate to which the sponge is glued. Two adjustable stop bolts should be placed in the corners of the base plate such that the ends of the bolts extend nearly to the top edge of the sponge.

For measuring a salamander, the device is opened so that the salamander can be placed on the inside surface of the transparent cover plate (the surface opposite the sponge). Before the salamander is placed (ventral side down) on the cover plate, the cover plate should be wetted. In the field, it is convenient to carry a small squirt bottle of water for this purpose. The device is then tilted so that to move forward, the salamander would have to ascend the tilted cover plate. Because the cover plate is wetted, the salamander cannot achieve sufficient traction to ascend the plate. If the salamander is prodded at the tail, the animal will generally attempt to climb the plate, and although its forward motion is retarded,

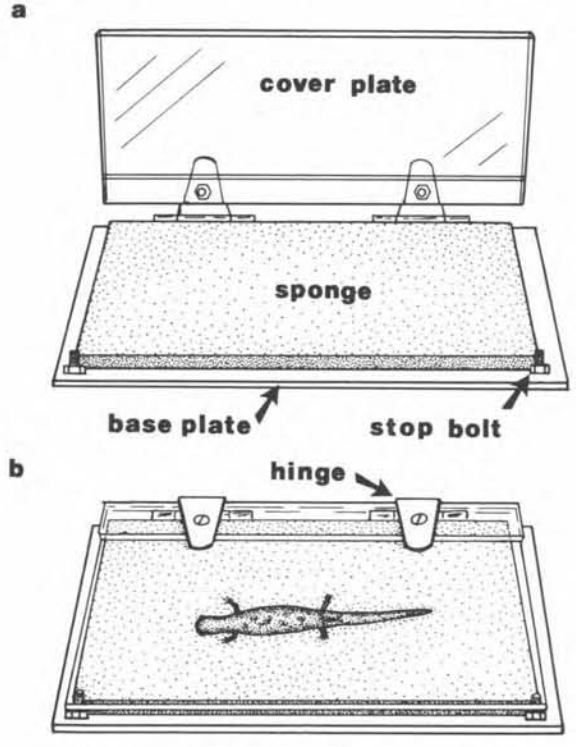

FIG. 1. An apparatus for measuring salamanders. (a) The open apparatus. (b) The ventral surface of a salamander pressed against the transparent cover plate of the closed apparatus.

its body will straighten. Then the base plate can be shut quickly on top of the cover plate, trapping the salamander in the cushioned sponge. The sponge prevents the salamander from moving and the stop bolts prevent the salamander from being crushed by maintaining a space between the base and cover plates. The apparatus can then be held shut by hand, or with a clothespin, rubber band, or similar device. After the salamander has been immobilized, if the tip of the tail is not straight, a thin object (such as a straightened paper clip or the metal rod that extends from calipers when in an open position) may be inserted between the sponge and the cover plate, and the tail may be manipulated into a straight position. The straightened salamander's ventral surface is now fully visible through the transparent cover plate, and measurements can be obtained using calipers or a ruler. The entire process of preparing a salamander for measurement generally requires approximately 30 s.

This basic design can be modified for larger salamanders by making the cover and base plates larger, using a thicker sponge, and adjusting the stop bolts to a longer length. Also, a simpler model can be made by replacing (1) the hinges with duct tape, (2) the stop bolts with blocks of wood or lids to bottles, (3) the cover plate with a piece of glass (tape the edges with duct tape to prevent the glass from breaking), and (4) the base plate with any thick rigid material that will hold the glued sponge (e.g., plastic), or the sponge can be taped to the base plate using duct tape. The aluminum/Plexiglass design is recommended over modified designs for field conditions because it is both lightweight and durable.

LIFE HISTORY NOTES

Life History Notes is analogous to Geographic Distribution. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword which best describes the nature of their note (e.g., Reproduction, Longevity, Morphology, etc.). Figures are permissible to illustrate any data, but should **replace** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance.

Standard format for this section is as follows: SCIENTIFIC NAME (in caps), COMMON NAME (lower case, in parentheses) as it appears in Collins (1990. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 3rd ed., Herp. Circ. 19:1-41), KEYWORD (in caps). DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (Name(s) in caps, and address(es) in full). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this or a recent issue for citation format).

CAUDATA

PSEUDOTRITON RUBER RUBER (Northern Red Salamander). **DIET**. Although *Pseudotriton ruber* feeds primarily on small invertebrates, adults occasionally prey on other salamanders (Martof et al. 1980. Amphibians and Reptiles of the Carolinas and Virginia. Univ. North Carolina Press, Chapel Hill, 264 pp.) including *Plethodon cinereus* (Dunn 1926. Salamanders of the Family Plethodontidae. SSAR, 1972, 446 pp.). However, no information is available on the size of the salamanders consumed. On 16 October 1991, we collected two juvenile *P. ruber* from beneath decayed logs in the middle of a spring-fed stream (Denison University Biological Reserve, Granville, Licking Co., Ohio). The salamanders were brought back to the laboratory, placed in 0.2% chloretone anesthetic solution, measured with digital calipers, weighed, and allowed to recover overnight in a shallow pan of spring water. The following morning, we discovered that one juvenile (SVL=47.76 mm, TL=74.70 mm, HW=7.21 mm, mass=2.32 g) had regurgitated an adult lead-backed phase *P. cinereus*. Although the body was partially digested, the tail of the regurgitated *P. cinereus* was intact and measured 32.95 mm. The *P. ruber* (SVL=52.3 mm, TL=87.2 mm, HW=7.9 mm, mass=3.67 g) was then sacrificed, and it also contained a *P. cinereus*. The tail of this *P. cinereus* was intact and measured 38.37 mm.

We sampled 21 *P. cinereus* on 17 October 1991. The size of the regurgitated *P. cinereus*, based on linear regressions of measurements from this sample, was estimated to be: SVL=36.2 mm, TL=69.1 mm, HW=4.1 mm, mass=0.64 g, while that from the stomach of the larger *Pseudotriton* was SVL=39.4 mm, TL=77.8 mm, HW=4.4 mm, mass=0.78 g.

Although there was a considerable difference between predators and prey in HW and mass, the two *P. cinereus* were only 5.59 mm shorter (TL) and 9.41 mm (TL) than the two juvenile *P. ruber*.

ANURA

PIPA CARVALHOI (NCN). **BEHAVIOR**. On 23 February 1990, while crossing the Sierra Negra on Highway 90 PE in Pernambuco, Brasil, we stopped on a bridge over the Tacuaritinga River about 3 km E of Vertentes. Summer had been dry and the river was well below its normal level, but some pools were left by the side of the main stream. We reached the river at about 1130 hrs. Skies were clear and air temperature was 35°C.

In one spot, four small, continuous overflow pools were separated from the river by an area of grasses and a small mound covered by shrubs. The depth of the pools did not exceed 10 cm. Several small black frogs were observed jumping in various directions out of the water. We observed frogs crawling rapidly among cushion plants in grass about 35 cm tall. Only one animal was observed jumping over the tops of the grass. We identified the frogs as *Pipa carvalhoi*. About 40 to 50 individuals were observed.

Most authors have indicated that *Pipa carvalhoi* is fully aquatic, but this report agrees with Myers and Carvalho (1945. Bol. Mus. Nacional [N.S] 35:1-24) that they can walk, jump, and do other activities out of the water. One of us (JEP) has observed similar activity in *Pipa parva* in northwestern Venezuela and northeastern Colombia where, far from the ponds, the frogs walk or jump in a very cumbersome elliptic curve, reaching a height of 70 cm but covering a distance of no more than 40 cm.

We thank CONICIT and the Universidad de Los Andes in Venezuela, and CNPq and the Universidad Estadual de Campinas in Brasil for financing a project (P1-011) devoted to the comparison of herpetofaunas.

Submitted by **JAIME E. PEFAUR**, Ecologia Animal, Facultad de Ciencias, Universidad de Los Andes, Mérida 5101, Venezuela, and **ADAO JOSE CARDOSO**, Departamento de Zoologia, I.B., Universidad Estadual de Campinas, Campinas, S. P., Brasil.

RANA SPHENOCEPHALA (Southern Leopard Frog). **VARIATION**. On 7 April 1990, I collected a dorsally unspotted *Rana sphenocephala* (62 mm SVL) near the Rt. 190 Sabine River overpass, ca. 3 km E of Bon Wier, Newton County, Texas (T.4S, R.12W, Sec. 5, NE 1/4). The specimen has several dark spots and bars on its hind limbs (Fig. 1). The phenotype of this specimen is similar to that of the *burnsi* morph in *R. pipiens* (Merrell 1965. Evolution 19:69-85). Unspotted specimens of *R. sphenocephala* have been reported from New Jersey, Alabama, Kentucky, eastern Mississippi, and southern Illinois (Brown and Funk 1977. Herpetologica 33:290-293).

FIG. 1. Unspotted *Rana sphenocephala*, FMNH 241347.

The specimen was caught in a water-filled tire rut. Surrounding habitat consisted of a sandy river bank, and extensive bottomland forest. The specimen was deposited in the Field Museum of Natural History, Chicago, Illinois (FMNH 241347).

I thank R. A. Brandon, Southern Illinois University at Carbondale, for comments on this manuscript.

Submitted by **MICHAEL REDMER**, 21 West, 103 Par Lane, Itasca, Illinois 60143, USA.

TESTUDINES

GOPHERUS POLYPHEMUS (Gopher Tortoise). **DIET**. Grasses and legumes comprise a major portion of the diet of *Gopherus polyphemus*, but rare instances of coprophagy and carrion feeding have been reported (Garner and Landers 1981. Proc. Ann. Conf. S. E. Assoc. Fish & Wildl. Agencies 35:120-134). We report here on two additional observations of *G. polyphemus* feeding behavior.

On 18 May 1989, on of us (REH) observed a small adult *G. polyphemus* (20.5 cm CL) feeding on fox scat by the edge of a dirt road, 16 km SW of Butler, Taylor Co., Georgia. The remaining scat consisted primarily of small mammal hair.

On 19 August 1989, we located a road-killed adult male *G. polyphemus*, 25 km NW of Sopchoppy, Wakulla Co., Florida. Inspection of the stomach contents revealed several teeth and intact ribs that were later identified to be from a small opossum (*Didelphis virginiana*). The opossum also probably was a road fatality, although the carcass was not located. We thank Dick Franz for confirming the identification of the skeletal material.

Submitted by **OWEN F. ANDERSON**, Institute of Natural Resources, University of Georgia, Athens, Georgia 30602, USA, and **ROBERT E. HERRINGTON**, Department of Biology, Georgia Southwestern College, Americus, Georgia 31709, USA.

GOPHERUS POLYPHEMUS (Gopher Tortoise). **DIET**. The diet of *Gopherus polyphemus* in the western parts of its range is poorly known, and probably differs from that in the east, where *Aristida* is a major dietary component (MacDonald and Mushinsky 1988. Herpetologica 44:345-353). Lohoefner and Lohmeier (1981. J. Herpetol. 15:239-242) observed tortoises feeding on grasses (*Digitaria sanguinalis* and *Panicum* spp.) in southern Mississippi.

On 24 April 1991, I observed a juvenile *G. polyphemus* (ca. 9 cm long) foraging on a sunny hillside on the Chickasawhay Ranger District of the DeSoto National Forest, Wayne County, Mississippi (T.6N, R.8W, Sec. 26). At 1542 hrs CDST this tortoise was eating leaves of lupine (Fabaceae: *Lupinus diffusus*) and morning glory (Convolvulaceae: *Stylisma* sp.). The animal took a couple of bites from each plant before moving to the next. At 1600 hrs CDST it entered a burrow ca. 9 cm diam. I thank W. McDearman for verifying plant identifications.

Submitted by **C. A. JONES**, Mississippi Museum of Natural Science, 111 N. Jefferson St., Jackson, Mississippi 38201, USA.

LEPIDOCHELYS KEMPII (Kemp's Ridley Sea Turtle). **REPRODUCTION**. Mating by *Lepidochelys kempii* in the wild has not previously been documented. There are anecdotes of mating pairs in Mexican waters offshore from coastal Tamaulipas and Veracruz, before the nesting season commences (about 1 April) or during the nesting season (April-July) (R. Byles, pers. comm.). The first confirmed observation of *L. kempii* mating in Texas waters was made on 3 June 1991. Mr. Walt Kittleberger observed and photographed a pair of turtles in the Mansfield Channel, Willacy Co., Texas, ca. 230 m E of marker 22 (26°33'35"N, 97°22'25"). Mr. Kittleberger related that the pair was first observed at 1200 h. The male had mounted the female and both turtles were on their sides, at the surface, in the center of the channel. They soon turned so that their carapaces were upward, with the male located above the female. The pair submerged for 30 s periods and drifted N out of the channel with an outgoing tide. Diving depths could not be detected because of murky water conditions. They were last seen at 1315 hrs, still coupled and in water ca. 0.6 m deep within the lower Laguna Madre.

Mr. Kittleberger forwarded his photographs to me, and I identified the turtles as *L. kempii* based upon color, shape of the carapace, and size. Identity of the turtles was verified independently by R. Byles, U.S. Fish and Wildlife Service, Albuquerque, New Mexico. I could not determine whether they were wild or individuals from an attempt to establish a secondary breeding colony of this species at Padre Island National Seashore (Shaver 1990. Park Science 10(1):12-13), because tags, tag scars, or living tags could not be seen. No sea turtle nests were found along the Texas coast subsequent to the mating.

This is also the first documentation of this species within Willacy Co. inshore waters (including the Mansfield Channel and lower Laguna Madre) and the first observation of mating in inshore waters. The photographs were deposited in the collection at Padre Island National Seashore (PAIS 2520), Corpus Christi, Texas. I thank Richard A. Byles for his comments.

Submitted by **DONNA J. SHAVER**, National Park Service, Padre Island National Seashore, 9405 S. Padre Island Drive, Corpus Christi, Texas 78418-5597, USA.

SAURIA

ANOLIS CAROLINENSIS (Green Anole). **MAXIMUM SIZE**. Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed., Houghton Mifflin Co., Boston, 450 pp.) give the maximum size of *Anolis carolinensis* as 203 mm TL and 75 mm SVL. This appears to be a typographical error, because in 1986 I informed Collins of Tulane 19830 that had a 208 mm TL. Dundee and Rossman (1989. The Amphibians and Reptiles of Louisiana, Louisiana State University Press, Baton Rouge, 300 pp.) gave the 208 mm figure. Overlooked by me was an uncataloged specimen, now Tulane 20781, taken in 1979, that measured 209 mm TL in life (it now measures 208 mm in preservative). Subsequent to the publication of Dundee and Rossman, on 22 June 1989 I captured a specimen, now LSUMZ 53000, that measured 209.5 mm TL. All three of these very large males were taken from the yards of my previous and present homes in New Orleans and its suburb, Metairie, Louisiana. The largest SVL of any of these specimens is 70.5 mm, substantially less than the maximum of 75 mm reported

by Conant and Collins. Five new specimens, however, taken between 3 October and 19 October 1991 in the vicinity of Sorrento, Ascension Parish, Louisiana, and brought by collectors to Buck Prima, a commercial reptile dealer at LaPlace, Louisiana have the following measurements: LSUMZ 53620, SVL 73 mm, TL 211 mm; LSUMZ 53621, SVL 73 mm; LSUMZ 53622, SVL 79.5 mm, TL 227 mm; LSUMZ 53623, SVL 76.5 mm, TL 217.5; LSUMZ 53624, SVL 74 mm, TL 220 mm. A sixth specimen, LSUMZ 53625, taken 24 October 1991 near Sorrento, measures 80 mm SVL, 231 mm TL, and appears to have ca. 1 mm of tail missing.

Submitted by **HAROLD A. DUNDEE**, Department of Ecology, Evolution, and Organismal Biology, Tulane University, New Orleans, Louisiana 70118, USA.

LIOLAEMUS LUTZAE (Sand Lizard). **CANNIBALISM**. Intraspecific predation or cannibalism is a behavioral trait widespread within animal groups (Fox 1975. Ann. Rev. Ecol. Syst. 6:87-109; Polis 1981. Ann. Rev. Ecol. Syst. 12:225-251). Intraspecific predation of juveniles by adult lizards has been reported in some species (Hews 1989. Herpetol. Rev. 20(3):71; Polis and Myers 1985. J. Herpetol. 19:99-107; Wilson 1990. Herpetol. Rev. 21(3):61-62). During a study on seasonal variation in feeding habits I examined the stomach contents of 58 adults of *Liolaemus lutzae* (collected from December 1985 to December 1986) from coastal sand dune habitats of southeastern Brazil. Two of the lizards (1.3%), both males (67.2 and 67.6 mm SVL) had conspecific juveniles (29.0 and 30.0 mm SVL, respectively) in their stomachs. One stomach (collected 18 February) was entirely occupied by an undigested juvenile, and the other (collected 14 January) had a partially digested juvenile together with other prey items (coleopteran, ants, and lepidopteran larvae) common to *L. lutzae* (Rocha 1989. J. Herpetol. 23(3):292-294). That both predators were male supports the observation of Wilson (1990), who suggested that sexual differences in frequency of cannibalism could be related to the larger size of the males. *L. lutzae* males are significantly larger in body and head size (Rocha 1989. Masters Thesis. Universidade Estadual de Campinas, Campinas, São Paulo, Brazil, 104 pp.). Both instances of cannibalism occurred in the summer when *L. lutzae* is at peak abundance. This supports the conclusion that these observations represented opportunistic foraging (Polis and Myers, op. cit.). I thank Helena Bergallo for suggestions on the text and the Fundacão de Amparo a Pesquisa de Estado do Rio de Janeiro for financial support (process No. E-29 1708864/90).

OPHISAURUS VENTRALIS (Eastern Glass Lizard). **REPRODUCTION**. On 10 August 1990, an adult *Ophisaurus ventralis* and six eggs were dug up by workers at the Back Bay National Wildlife Refuge, Virginia Beach, Virginia. The adult lizard escaped and the eggs were collected. The eggs were measured and placed in moist sandy soil from the capture location and allowed to continue development. The six eggs measured 21.0 x 13.8 mm, 22.2 x 13.3 mm, 20.7 x 13.4 mm, 21.0 x 13.4 mm, 21.0 x 14.1 mm, and 20.0 x 13.4 mm, similar in size to eggs deposited in June and July (Schwab 1988. Catesbeiana 8(2):31). On 19 August 1990, three eggs hatched. On 20 August 1990, the remaining three eggs were opened and contained three dead but fully formed lizards. The three dead specimens were preserved and measured (TL = 123, 124, and 139 mm).

Submitted by **DONALD J. SCHWAB**, Virginia Wildlife Division, P.O. Box 847, Suffolk, Virginia 23434, USA.

UROSAURUS ORNATUS (Tree Lizard). **MORTALITY**. While conducting observations on the social behavior of tree lizards in outdoor enclosures during the reproductive seasons of 1988 and 1990, several lizards died. There was an apparent relationship between those males that succumbed and their social status, as well as between the number of lizards that died and the air temperature.

The experiments were conducted in 2 m x 4 m x 0.5 m high sheet metal pens with cinder blocks for perching and hiding. All pens were housed within a chainlink fence and were covered on the top and sides with chicken wire to prevent avian and mammalian predation. One female and three males were present in each pen. In June 1988, nine groups of three males were matched for size and throat coloration and in June 1990, ten groups of three males were matched for size but differed in throat coloration. The lizards for both sets of experiments were collected from the Doña Ana Mountains, 25 air km NNE of Las Cruces, Doña Ana County, New Mexico. In all pens, a dominance hierarchy arose in which one male assumed the high ranking position; he was the only male in each group to perform dominance displays such as assertions, challenges, and chases.

Temperature differed between years. The mean maximum air temperature was 34.4°C in June 1988 and was 37.8°C in June 1990. In June 1988 no days reached above 38°C, while in June 1990, 17 days did so. Mean June maximum from 1870-1987 is 34.4°C. In both years, observations were made from about 0630 to 0900 hrs. Initial and ending air temperatures were significantly higher (t-test; $P<0.001$) in 1990 compared to 1988. In 1988, one of 27 males, a subordinate, either died or managed to escape from the pen during the course of the experiment. In 1990, eight of 30 males died; all were subordinates. They died between 10 and 22 days after being placed in the pens (each experiment ran for 28 days). Thus, significantly more subordinates died than dominants (log-likelihood ratio $G = 8.12$; $P = 0.004$), and significantly more lizards died in 1990 than in 1988 ($G = 6.37$; $P = 0.012$).

Differences in survivorship during the course of the two experiments were more likely explained by heat stress in 1990 as opposed to differences in severity of injury suffered by subordinate males. Dominant males in 1990 were not more aggressive (based on number of dominance behaviors performed) than those in 1988 (unpubl. data). Subordinate males might be more susceptible to heat stress due to minor injuries inflicted by dominant males, or, dominant males may have been able to keep subordinate males away from cooler microhabitats. In either case, one benefit of being a dominant individual appears to be an increased chance of survival during periods of environmental stress, especially in populations with high densities and limited territorial sites as occurred in these experiments and sometimes in the wild (Zucker 1989. J. Herpetol. 23:389-398).

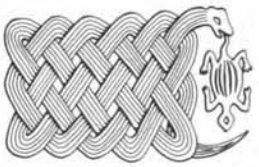
SERPENTES



FARANCIA ABACURA ABACURA (Eastern Mud Snake). **REPRODUCTION**. Parental care of eggs in *Farancia abacura* was confirmed by Meade (1940. Herpetologica 2:15-20), Goldstein (1941. Copeia 1941(1):49-50), and Riemer (1957. Herpetologica 13:31-32). Parental care is a rare behavior in snakes, reported in 2.8% of the suborder (Shine 1988. *In* Gans and Huey (eds.), Biology of the Reptilia, vol. 16, Alan R. Liss Inc. New York, pp. 276-329). On 18 September 1991 a female *F. a. abacura* (1380 g, 145 cm TL) was discovered sitting on a clutch of eggs. The nest was in discarded potting soil in a self-constructed chamber (30 cm x 21 cm x 11 cm from soil to top of snake). A pad of 6 cm thick, loosely rooted soil rested directly on the snake. The nest was at an open disturbed site on level ground beside a greenhouse, 15 m up a slight incline from the SE side of Lake Alice on the campus of the University of Florida, Gainesville (T.10S., R.20E., Sec. 7). The female was tightly coiled on top of 53 nonadhesive eggs in a double layer, with none of the eggs visible from above. Seven eggs were damaged, with three very dry, two quite dry, and two recently punctured (probably not slit by hatchlings) and nearly fully hydrated. All damaged eggs were in the bottom layer in the nest, and the punctures faced the soil. The top of the clutch was practically free of loose soil, indicating the snake may not have left the nest since the eggs were laid. The temperature of the nest at the top of the eggs under the female was 27.0°C at 1500 hrs. Both female and clutch were removed to the laboratory.

Length of 46 viable eggs varied from 30.0–38.3 mm ($\bar{x}$ = 31.8 mm, SD = 6.54); width varied from 20.3–24.7 mm ($\bar{x}$ = 22.9 mm, SD = 0.96); and mass varied from 7.90–10.96 g ($\bar{x}$ = 9.41 g, SD = 1.50). Assuming the mean mass of the seven damaged eggs was the same as the mean mass of undamaged eggs, the total clutch mass was 507.8 g or 36.8% of the female mass.

The eggs were spaced out on top of moist soil in a closed container and incubated at an undetermined room temperature. The soil was taken from the walls of the nest chamber. Until water was added to this soil three hours after the eggs were removed from the nest, dehydration caused a significant dimpling of each egg. Hatching began at ca. 2200 hrs on 22 September, just over four days after removal from the nest. Eighteen hours elapsed from first slit to first emergence, at which time 24 of the 46 eggs were slit. Successful emergence of all 46 hatchlings took place at a constant rate, requiring 50 hrs from first slit to last emergence at midnight on 24 September. Hatchlings made 1–12 straight slits in the shell ($\bar{x}$ = 4.8, SD = 2.2), usually less than 1 cm long and mostly restricted to the top and one half of the egg. I observed heads of hatchlings extended partially outside the slit, but they quickly withdrew when disturbed. Hatchling mass varied from 4.47–7.53 g ($\bar{x}$ = 6.91 g, SD = 0.52) and TL varied from 198–242 mm ($\bar{x}$ = 221 mm, SD = 9.7). Eggshell mass (air-dried) varied from 0.11–0.23 g ($\bar{x}$ = 0.16 g, SD = 0.02). Almost all hatchlings remained in a tight clump for the first night following emergence.

Eight hatchlings were retained in a shallow water aquarium, and all shed over a 44-hr period, starting at 2200 hrs on 2 October, almost eight days after completion of hatching. During their sixteen days before release, the eight hatchlings did not eat, despite being offered, live earthworms, freshwater shrimp, and small fish (*Gambusia affinis*).

HANDBOOK TO MIDDLE EAST AMPHIBIANS AND REPTILES

by Alan Leviton, Steven Anderson, Kraig Adler, and Sherman Minton

THIS BOOK covers the amphibians and reptiles of the region extending from the Turkish border through Iraq, Kuwait, and northern and eastern Saudi Arabia, including the Arabian (Persian) Gulf and the lowlands surrounding it (southwestern Iran, Bahrain, Qatar, and the United Arab Emirates). This is the first field guide to the herpetofauna of the Middle East and features:

- Diagnosis, description, and distribution of each taxon;
- Illustrated keys to all genera, species, and subspecies;
- Additional chapters on venomous snakes, snakebite, and treatment;
- Extensive bibliography of Middle East herpetology;
- Appendix on collecting and preserving techniques by John E. Simmons;
- Text: 260 pages, 23 text figures, 2 maps;
- 32 color plates: 210 individual photographs of animals and habitats; All 75 genera and 85% of the species are illustrated in color;
- Format: 7 x 10 inches, clothbound;
- Price: $28 plus shipping (USA: $2.00; outside of USA: $3.25).

Send orders to: Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, St. Louis University, St. Louis, Missouri 63103. Make checks payable to "SSAR." VISA and MasterCard accepted (provide card number and expiration date). Complete list of SSAR publications on request.

Submitted by **DAVID L. AUTH**, Herpetology Division, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA.

THAMNOPHIS PROXIMUS RUTILORIS (Western Ribbon Snake). **NATURAL HISTORY**. During the spring and summer of 1985 we captured eight active adult *Thamnophis proximus* during a study of diet and activity patterns of the water snake *Nerodia rhombifera* in a swamp in the mouth of Papaloapan River in Alvarado Port (18°46'N, 95°44'W), Veracruz, México. Two males (370 and 395 mm SVL) and six females (290–415 mm SVL), were captured. Snakes were forced to regurgitate and all had fed on frogs (*Leptodactylus melanonotus*, n = 7 stomachs), or toads (*Bufo valliceps*, n = 1). Five species of small fish present in the swamp were not found to be consumed. Snakes were active during daylight hours in the grasslands surrounding the swamp. Although we searched for snakes during monthly visits from March 1985 to June 1986, we found them only between March and October 1985, coinciding with periods of high abundance of anurans.

On 12 October 1985 at 1015 hrs, we observed an adult female *Thamnophis proximus* (290 mm SVL) arrive at the pond, where she was attacked and killed by an aquatic bug (Belos-

tomatidae). The neck of the snake had been grasped with the claws and the head of the snake was submerged. Air temperature was 26°C. There are few published reports of invertebrates preying upon amphibians or reptiles, and this parallels a single report of predation on snakes by a diving beetle larva (Drummond and Wolfe 1981. Coleop. Bull. 35(1):121-124).

On 15 June 1985, one gravid female (410 mm SVL) was collected and transported to the laboratory and on 21 August gave birth to four males (150-158 mm SVL) and two females (155 and 157 mm SVL).

Submitted by **JAVIER MANJARREZ**, and **CONSTANTINO MACIAS-GARCIA**, Centro de Ecología, Universidad Nacional Autonoma de México, AP 70-275, CP 04510, Ciudad Universitaria, DF, México.

GEOGRAPHIC DISTRIBUTION

Three Species New To The Herpetofauna Of New Mexico

While no comprehensive up-to-date treatment of the herpetofauna of New Mexico exists, work is currently underway to compile that information (Degenhardt, Painter, and Price, in prep.). This accelerated interest in the distribution of New Mexico's amphibians and reptiles led to recent collections that have yielded three species new to the herpetofauna of New Mexico.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). Doña Ana Co: Las Cruces, trailer court on Stearn Drive, ca. 4 km S jct El Paseo Drive. 10 September 1991. John Waters. Verified by Geoff C. Carpenter. New Mexico State University (NMSU 6612). Numerous specimens have been collected at the above and nearby localities. All collection sites have been associated with human dwellings. The establishment of a population of *H. turcicus* in Las Cruces is not surprising, as a population has been known to exist in El Paso, Texas, for almost ten years (Selcer 1986, Copeia 1986(4):956–962; R. G. Webb, pers. comm., UTEP 9539).

LAMPROPELTIS ALTERNA (Gray-banded Kingsnake). Eddy Co: Carlsbad Caverns National Park. DOR on New Mex. Rt. 7. 15 June 1991. Gary & Shane Swinford. Verified by W. G. Degenhardt. University of New Mexico Museum of Southwestern Biology (MSB 52000). The occurrence of this secretive species in adjacent Texas is well documented and its presence in southeastern New Mexico (Guadalupe Mountains) is not unexpected (Gehlbach 1967, Cat. American Amphib. Rept. 55.1–55.2). This specimen was collected under the authority of a Carlsbad Caverns National Park scientific collection permit and will be considered for listing as state-endangered by the New Mexico State Game Commission. Unconfirmed sight records exist for this species in the western foothills of the Guadalupe Mountains and on Otero Mesa.

TANTILLA YAQUIA (Yaquia Blackhead Snake). Hidalgo Co: Peloncillo Mountains, Skeleton Canyon, ca. 27.4 km S Rodeo, Sec 24, T31S, R22W. 25 August 1991. Paul W. Hyder. Verified by Joseph L. LaPointe. New Mexico State University (NMSU 6618). Because this species is often encountered in the riparian woodland near Portal in the Chiricahua Mountains of southeastern Arizona (McDiarmid 1977, Cat. American Amphib. Rept. 198.1–198.2), its presence in similar habitat in New Mexico is not unexpected.

New County Records For Amphibians And Reptiles From Pennsylvania

McCoy (1982, Amphibians and Reptiles of Pennsylvania: Checklist, Bibliography, and Atlas of Distribution. Spec. Publ. Carnegie Mus. Nat. Hist. (6):1–91) provided the first recent treatment of the distribution of the herpetofauna of Pennsylvania. This extensive work has added much to our knowledge of the state's herpetofauna, yet many gaps in the distribution of individual species remain to be filled. All specimens in this report constitute new county records. Unless otherwise stated all specimens were collected by the authors, and are deposited in the Carnegie Museum of Natural History (CM). Identifications have been verified by C. J. McCoy.

CAUDATA

CRYPTOBRANCHUS A. ALLEGANIENSIS (Eastern Hellbender). Forest Co: Tionesta Creek at Kelletville. 25 August 1991. CM 123202. Tionesta Creek, 1.3 km downstream from confluence with Minister Creek. 25 August 1991. CM 123203.

NECTURUS M. MACULOSUS (Mudpuppy). Forest Co: Tionesta Creek, 2.2 km upstream from mouth of Blue Jay Creek. 2 August 1991. CM 123204.

AMBYSTOMA JEFFERSONIANUM (Jefferson Salamander). Adams Co: 8 km S Pine Grove Furnace State Park on Rt. 233. 15 June 1989. CM 119143. Erie Co: Harborcreek Twp., Behrend College, Station Rd. 26 March 1987. M. Lethaby. CM 115957. Franklin Co: Michaux State Forest, 2.5 km S Old Forge. 19 May 1987. R. W. Van Devender. CM 116340–42. McKean Co: Fuller Brook Creek on Glendora Estate, 1.6 km W Corydon St. 26 March 1987. T. Pauley. CM 119101–102.

AMBYSTOMA OPACUM (Marbled Salamander). Leigh Co: Penn. Gameland Unit 217, 0.2 km SW Bake Oven Knob on Appalachian Trail. 27 November 1984. M. R. Collie. CM 113362. Monroe Co: Snowhill Rd, 6.4 km E Rt. 447. 24 May 1990. CM 123158–159.

NOTOPHTHALMUS V. VIRIDESCENS (Red-spotted Newt). Armstrong Co: Spring Church. 10 April 1991. CM 123194–3200. Greene Co: pond below the causeway at the SW edge of Ryerson Station State Park. 5 May 1990. CM 123155.

DESMOGNATHUS OCHROPHAEUS (Mountain Dusky Salamander). Huntingdon Co: along Little Juniata River, 1.2 km upstream from Rt. 305 on Twp. Rd 492. 7 June 1989. CM 123126. Pike Co: pond eddy along the Delaware River. 23 May 1990. CM 122157. Partly fills in the distribution of this species along the southern edge of the Valley and Ridge Province and along the northeastern corner of the state.

GYRINOPHILUS P. PORPHYRITICUS (Northern Spring Salamander). Adams Co: Caledonia State Park near Hosack Run Campground. 19 June 1989. R. W. Van Devender. CM 118756. Greene Co: Legislative Rt. 30039, 1.1 km SE Ryerson Station State Park. 4 May 1990. CM 122156. Confirms the presence of this species in the southwestern corner of the state.

PLETHODON WEHRLEI (Wehrle's Salamander). Clarion Co: Penn. State Gameland 74 on Mill Creek, 0.8 km upstream from Legislative Rt. 16055. 1 April 1981. R. McPherson. CM 89574.

PSEUDOTRITON R. RUBER (Northern Red Salamander). Elk Co: Belle Draft Rd, 5.4 km N Dents Run Rd in Elk State Forest. 8 June 1991. CM 123193. Forest Co: Pigeon Hill Rd, 3.3 km E Rt. 62. 25 May 1988. CM 118452–453. McKean Co: Willow Creek, under bridge on Forest Rd 602. 28 May 1985. T. K. Pauley. CM 112204.

EURYCEA BISLINEATA (Northern Two-lined Salamander). Forest Co: West Hickory Creek at Rt. 227. 17 August 1989. CM 119141–142.

EURYCEA L. LONGICAUDA (Longtail Salamander). York Co: Anderson Creek at Lock No. 12 Picnic area along Susquehanna River. 8 July 1989. CM 119140. Fills in a gap in the distribution of the species along the southern border of the state.

ANURA

BUFO A. AMERICANUS (Eastern American Toad). Jefferson Co: Rt. 949 at entrance to Clear Creek State Park. 21 July 1989. CM 119144.

BUFO WOODHOUSII FOWLERI (Fowler's Toad). Greene Co: 4.8 km SE Rt. 21 on Legislative Rt. 30038. 4 May 1990. CM 123154. York Co: Susquehanna River at Lock No. 12. 7 July 1989. CM 119145. Yellow Breeches Creek at SR 74. 10 July 1989. CM 119146. Begins to fill in the distribution in the lower Susquehanna drainage.

HYLA VERSICOLOR (Gray Treefrog). Erie Co: Presque Isle State Park near waterworks. 23 May 1989. D. M. McKinstry & H. N. Cunningham. CM 119119.

PSEUDACRIS C. CRUCIFER (Northern Spring Peeper). Adams Co: Quarry Gap at Penn. Rt. 233. 20 May 1987. R. W. Van Devender, CM 118708. Luzerne Co: Lake Jean. 6 June 1990. CM 123173.

RANA CATESBEIANA (Bullfrog). Forest Co: Tionesta Creek, 1 km S confluence with Minister Creek. 16 August 1989. CM 123215.

RANA CLAMITANS MELANOTA (Green Frog). Susquehanna Co: Martin's Creek at Rt. 11, 18 km N county line. 1 June 1990. CM 123165–168.

RANA PALUSTRIS (Pickerel Frog). Greene Co: N Fk of Dunkard Fork, 0.5 km W Ryerson Station State Park. 21 May 1989. CM 119150.

RANA SYLVATICA (Wood Frog). Adams Co: 8 km S Pine Grove Furnace State Park on Rt. 233. 15 June 1989. CM 119147–148. York Co: Bald Eagle Creek, 3 km N Rt. 851 on Rt. 425. 8 July 1989. CM 119149. Fills in the species range in the southern border counties.

TESTUDINES

APALONE SPINIFERA SPINIFERA (Eastern Spiny Softshell). Clarion Co: Allegheny River at mouth of Clarion River, 1.6 km N Parker. 22 August 1986. M. A. Ewert. CM 114446. Mercer Co: Shenanhgo Bridge at Reynolds Heights. 17 June 1987. M. A. Ewert. CM 117881.

CHELYDRA S. SERPENTINA (Common Snapping Turtle). Armstrong Co: Allegheny River, 3.2 km W Reston. 28 August 1986. M. A. Ewert. CM 114449. Bedford Co: Dunning Creek at Rt. 96, N New Paris. 30 June 1990. CM 123177. Raystown Branch of Juniata River in Bedford. 1 July 1990. CM 123178–179. Bradford Co: Rt. 414, 16.5 km W jct. with Rt. 220 near Towanda Creek. 6 June 1990. CM 123172. Elk Co: mouth of Mason Creek at Ridgeway. 1974. V. Rogers. CM 107451. Forest Co: Allegheny River, 1.6 km SSW Tionesta. 23 August 1986. M. A. Ewert. CM 114444. Montour Co: Penn. Rt. 44, 2.6 km W Exchange. 23 April 1982. G. J. and J. F. Jacobs. CM 116305. Northumberland Co: Rt. 147, 1.3 km S Rt. 45 along Susquehanna River. 15 June 1990. CM 119163. Codorus Creek at Rt. 616. 11 July 1989. CM 119162. Fills in the species range in the southern border counties and in the northeastern portion of the state.

CHRYSEMYS PICTA MARGINATA (Midland Painted Turtle). Cameron Co: near Sinnemahoning Creek along Rt. 555, 6.7 km E Cameron/Elk county line. 15 July 1991. CM 123187–88. 12.5 km S Potter County line on Rt. 872 near First Fork Creek. 15 July 1991. CM 123189–191. Sullivan Co: Rt. 154, 4 km N Rt. 220. 6 June 1990. CM 123175. Susquehanna Co: Martin's Creek along Rt. 11, 25 km N county line. 31 May 1990. CM 123163–164.

CLEMMYS INSCULPTA (Wood Turtle). Fulton Co: 0.8 km E New Grenada along Sideling Hill Creek. 2 June 1989. CM 119157. Somerset Co: Rt. 219, 5.4 km S jct. with Rt. 30. 24 July 1991. CM 123201. Begins to fill in the distribution along the southern border of the state.

CLEMMYS MULHENBERGII (Bog Turtle). New localities have been discovered in Adams and York counties and voucher specimens are on deposit at the Carnegie Museum, but due to the endangered status of the species the exact localities are being withheld.

TERRAPENE C. CAROLINA (Eastern Box Turtle). Armstrong Co: N end Keystone Lake. 31 July 1990. CM 123180.

SAURIA

EUMECES A. ANTHRACINUS (Northern Coal Skink). Elk Co: Elk State Forest, Belle Draft Rd, 5 km N Dents Run Rd. 27 July 1990. CM 123185. Somerset Co: 7.6 km S Somerset. May 1985. K. J. Stairs. CM 112207.

EUMECES FASCIATUS (Five-lined Skink). Erie Co: 0.8 km N Rt. 6, N off of Cherry Hill Rd, about 0.6 km W Albion. 24 April 1990. M. Lethaby and J. Tucci. CM 119167–168. Franklin Co: 4 km N Doylesburg on Rt. 274. 10 June 1989. CM 119155. Perry Co: Horse Valley Rd, 13.4 km NE Rt. 75. 10 June 1989. CM 119153–154.

SERPENTES

CARPHOPHIS A. AMOENUS (Eastern Worm Snake). Perry Co: Horse Vally Rd, 9.8 km NE Rt. 75. 28 April 1990. CM 123150.

COLUBER C. CONSTRICTOR (Northern Black Racer). Cameron Co: Rt. 555, 0.9 km W Houston Hill Rd. 15 July 1991. CM 123186. Clearfield Co: 1.1 km N Newtonburg on Twp Rd 333. 26 July 1989. CM 119132.

DIADOPHIS PUNCTATUS EDWARDSII (Northern Ringneck Snake). Blair Co: 3.6 km SE Martinsburg on Rt. 164. 1 June 1989. CM 119129–130. Greene Co: 11.6 km S Morrisville on Rt. 19. 19 May 1989. CM 119121. N Fork Dunkard Fork, 0.5 km W Ryerson Station State Park. 21 May 1989. CM 119123. Rt. 88, 21 km S jct. with Rt. 21. 21 May 1989. CM 119124–126. Rt. 18, 8.2 km N jct. with Rt. 21. 20 May 1989. CM 119122. Juniata Co: 3.2 km N of Perry County line on Rt. 74. 8 June 1989. CM 119159–160. Susquehanna Co: Rt. 262, 1.6 km S Choconut. 30 May 1990. CM 123160. Hwy 706, 1.5 km E Montrose. 30 May 1990. CM 123181–182. Rt. 295, 11 km S of New York State line. 30 May 1990. CM 123183. Fills in the species range in the southern and northeastern portions of the state.

ELAPHE O. OBSOLETA (Black Rat Snake). Chester Co: Freemont Rd, Nottingham Twp. 1987. D. Owens. CM 118320. Columbia Co: Rt. 118, 3.2 km E Rt. 239. 6 June 1990. CM 123171.

LAMPROPELTIS T. TRIANGULUM (Eastern Milk Snake). Armstrong Co: 1.5 km N Elderton, Plum Creek Twp. 19 June 1988. CM 118141. Fills in the species distribution in the western half of the state.

OPHEODRYS VERNALIS (Smooth Green Snake). Columbia Co: 2.7 km S Red Rock on Rt. 487. 4 June 1990. CM 123169. Susquehanna Co: 11.5 km S Choconut on Rt. 267. 30 May 1990. CM 123161. Rt. 11, 4.8 km S jct. with Rt. 31 May 1990. CM 123162.

REGINA SEPTEMVITTATA (Queen Snake). Lycoming Co: 8 km N Trout Run. 7 May 1949. G. Jacobs. CM 86826–28.

STORERIA D. DEKAYI (Northern Brown Snake). Columbia Co: Rt. 239, 6.5 km S jct. with Rt. 118. 6 June 1990. CM 123174. McKean Co: Forest Service Rd 602 near Warren County line. No date. T. Pauley. CM 115333. 0.8 km from Bridge over Willow Creek at Willow Bay. 4 May 1984. T. Pauley. CM 109051. Wyoming Co: River Street, Tunkhannock. 21 April 1957. G. C. Shaffer. CM 91540. York Co: York Furnace. 22 May 1987. R. W. Vandevender. CM 118719.

STORERIA O. OCCIPITOMACULATA (Northern Redbelly Snake). Berks Co: 0.4 km from Bird Creek at Camp Northkill, Upper Tulpenhocken Twp. 26 April 1986. J. A. Eckert. CM 114643. Columbia Co: Rt. 487, 2.7 km S Red Rock. 4 June 1990. CM 123170. Huntingdon Co: Rt. 994, 16 km E Trough Creek Road. 28 April 1990. CM 123151. Perry Co: Horse Valley Rd, 13.7 km NE Rt. 75. 28 April 1990. CM 123152–153.

THAMNOPHIS BRACHYSTOMA (Shorthead Garter Snake). Clearfield Co: 11.5 km N Mud Run Rd on Rt. 153. 23 July 1989. CM 119161.

THAMNOPHIS S. SAURITUS (Eastern Ribbon Snake). Bedford Co: Bard Rd, 3.3 km E Rt. 31. 22 June 1989. CM 119139.

THAMNOPHIS S. SIRTALIS (Eastern Garter Snake). Armstrong Co: 1.5 km N Elderton, Plum Creek Twp. 14 June 1988. CM 118144. Montour Co: Rt. 44, 3.7 km E Rt. 54. 6 June 1990. CM 71379.

VIRGINIA VALERIAE PULCHRA (Mountain Earth Snake). Clearfield Co: 7 km S Mud Run Rd on Rt. 153. 23 July 1989. CM 119133–134. 1 km N Mud Run Rd on Rt. 153. 23 July 1989. CM 119135. Elk Co: Belle Draft Rd, 5.4 km N Dent's Run Rd, Elk State Forest. 4 June 1991. CM 123192. Begins to fill in the gap in the species distribution in the north central portion of the state.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). ***HR*** especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Life History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints (8 x 10 inch preferred).

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc., 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Life History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles, Techniques Articles, Points of View, as well as news notes and other material, should be sent to the Editor.

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of three reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Life History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

RWH

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc. RFD 6 Box 1, Lawrence, Kansas 66046. *Herpetological Review* is composed using Microsoft Word and Aldus Pagemaker on Apple Macintosh computers. Camera-ready copy is produced on a Linotronic 230 Imagesetter at a resolution of 1700 dpi at Valley Type & Design, Fresno, California. All rights reserved. No part of this periodical may be reproduced without written permission of the editor.

SOCIETY FOR THE STUDY OF AMPHIBANS AND REPTILES

NEW PRICE for the

Catalogue Of American Amphibians And Reptiles

The catalogue consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere.

COMPLETE SET: NUMBERS 1 - 505	$190.00
INDEX TO ACCOUNTS 1 - 400: Cross-referenced, 64 pages	$5.00
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$5.00
IMPRINTED POST BINDER: (note - two binders are needed for the 505 accounts)	$25.00
INCOMPLETE SET: NUMBERS 1 - 190	$60.00
191 - 410	$70.00
411 - 505	$60.00

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the ***Journal of Herpetology*** (4 issues annually), ***Herpetological Review*** (4 issues annually), and occasional issues of ***Facsimile Reprints in Herpetology***. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1992

Student member	$25.00*	Sustaining member	$60.00*
Regular member	$35.00*	Contributing member	$85.00*
Institutional subscription	$60.00		

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles*** : subscriptionis $15.00 annually ($3.00 air delivery surcharge if airmail is desired.). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

1992 SSAR MEETING HIGHLIGHTS

Dates: 2-6 August 1992.

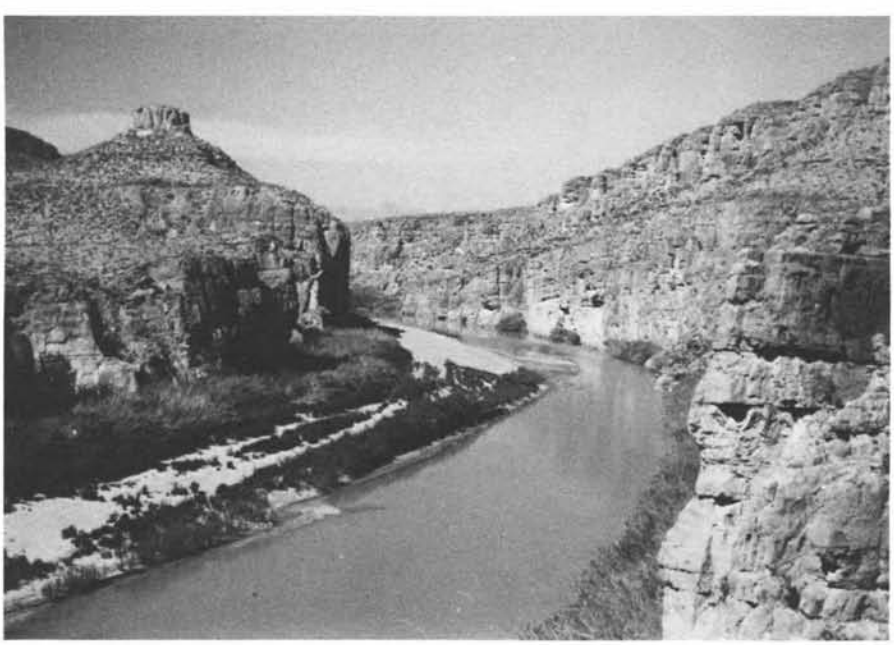
Place: University of Texas at El Paso (El Paso, Texas).

Co-host: El Paso Community College.

Co-sponsor: Sociedad Herpetología Mexicana.

Keynote Lecture: "A Random Walk Among the Anura," concerning the evolution and phylogenetics of frogs, by Linda R. Maxson (Pennsylvania State University).

Symposium: "Chelonian Systematics, Evolution and Zoogeography." *Organizers:* Edward O. Moll and John Carr. *Speakers:* John Bickham, Brian Bowen, John Carr, Charles Crumley, Brian Hanks, J. Alan Holman, John Iverson, John M. Legler, Jeff Lovich, Samuel B. McDowell, Peter Meylan, Pat Minx, Edward O. Moll, Anders G. J. Rhodin, and Roger Conant Wood.



Symposium: "Conservation of Amphibians and Reptiles." *Organizers:* Tom R. Johnson and Paul Moler.

Herpetological Travelogue Slide Shows: James R. Dixon (Venezuela), Aaron M. Bauer (Pacific Ocean and Australia), Aurelio Ramirez-Bautista (México), and Edward O. Moll (Turtles of South Asia).

Oral and Poster Presentations: Several concurrent sessions each day.

Student Paper Awards: Seibert Prizes will be awarded to the two best student papers ($250 first prize, $150 second).

Herpetological Art Show: A juried herpetological art show, at the Centennial Museum. $200 awards in each category: Best Painting, Best Drawing, Best Photo, and Best Sculpture. (Entry Form in the December 1991 *Herpetological Review*, p. 108).

Rio Grande and limestone cliffs near Rio Grande Village, Big Bend National Park, Texas. This is the lowest (600-610 m), driest area in the Chihuahuan Desert. Photo courtesy of T. R. Van Devender.

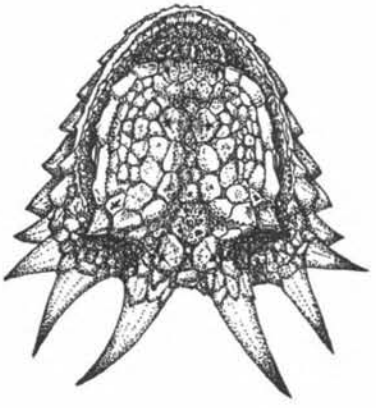
Audiovisual Shows: "Herps of the West," "Amphibians of the Appalachians" (updated), and "Herpetology Past and Present."

Field Trips: Chihuahuan Desert Research Institute in Alpine, Texas, including a BBQ cookout. Trips to Franklin Mountains Wilderness State Park (hiking trip) or an all-day visit to Indio Mountains Research Station.

Social Activities: Welcoming Reception; "Fajita Fiesta"; the annual SSAR Auction; trip to Ciudad Juarez, México (optional).

Live Exhibit: Collection of local and southwestern amphibians and reptiles, arranged by the El Paso Herpetological Society and Chihuahuan Desert Herpetological Society (set-ups for photography will be provided).

Regional Herpetological Societies Conference: "Federal and State Wildlife Laws and Regulations and How They Affect Regional Herpetological Societies." *Organizer* Eric M. Rundquist.



Toad (horned) burgers—a gastronomic highlight and conservation lowpoint to mark annual SSAR meeting. Photo courtesy of T. R. Van Devender.

Costs: Registration fee, regular $60, students $35. Housing: On campus dormitory $15 per night single, $8 per night double; Off campus hotels, ranging from $40 to $55 per night (details in Meeting Announcement to be mailed to SSAR members in March 1992).

Further details in the December 1991 issue of *Herpetological Review* (pages 107-109) or on request from Carl S. Lieb, Department of Biological Sciences, University of Texas at El Paso, El Paso, Texas 79968-0512, USA *(Telephone 915-747-5844)*.

Succulent desert scrub with ocotillo, blind prickly pear, and chino grass on limestone slopes near Rio Grande Village. Photo courtesy of T. R. Van Devender.

SSAR BUSINESS

SSAR Election Results

Results of the recent SSAR election are as follows:

President-elect (to serve as president for 1993): Thomas H. Fritts.

Secretary: J. Eric Juterbock (unopposed).

Treasurer: Douglas H. Taylor (unopposed).

Directors: Robin M. Andrews, Bern W. Tryon.

SSAR El Paso Meeting—Conservation Symposium Announcement and Extended Call for Papers

This is the third Conservation Symposium announcement to appear in HR and extends the deadline for abstracts until 15 June 1992. The SSAR Conservation Committee is planning a one-day symposium dedicated to conservation efforts for amphibians and reptiles. A number of papers have been selected but fall short of the number needed to warrant a one-day session.

The Conservation Symposium will be devoted to specific topics such as the conservation of taxonomic groups (sea turtles, iguanid lizards, high elevation frogs), regions (desert, rain forest, wetlands), and conservation/management methodology. Papers of particular interest will be those dealing with "hands on" projects directly related to habitat improvement, mitigation, reproductive enhancement, and restocking or relocation of rare or endangered amphibians and reptiles.

To be considered for participation in the Symposium at the El Paso meeting, send a typed abstract (200-300 words) with a cover letter, by 15 June 1992, to:

Tom R. Johnson
Herpetologist
Missouri Department of Conservation
P.O. Box 180
Jefferson City, Missouri 65102-0180, USA.

Notice: Request to Amend Constitution

The SSAR Board expects to discuss amending the Constitution and Bylaws to make them gender-neutral at the Board and Business Meetings conducted at the 1992 Annual Meeting in El Paso, Texas, 2-6 August.

New Regional Society Section Editor for HR

The new Section Editor for Regional Society News is Eric Rundquist. Information concerning regional society news, activities, address changes, etc. should be sent to him (address on inside front cover).

IN MEMORIAM

Ruth M. Zantzinger

On 8 November 1991 the herpetological community lost one of its most ardent and beloved members, Ruth M. Zantzinger, of Philadelphia. Ruth lost her fight against a hepatic carcinoma which was diagnosed late in September 1991. Many were stunned by the suddenness of Ruth's passing and deeply saddened for the loss to SSAR and the herpetological community, for Ruth had truly become, in the words of one colleague, the "Grand Lady of the Society."

A self-taught biologist and herpetoculturist, Ruth attended many national and regional meetings, and participated in numerous workshops and field trips. The national conferences of the American Association of Zoological Parks and Aquariums (AAZPA) and the International Herpetological Symposium (IHS) allowed Ruth to become acquainted with prominent leaders of the zoo and husbandry communities across the country. Thus, she aptly described her professional role as a liaison person between zoos, museums, and universities for programs in herpetological research and education. Her favorite, and the one professional society with which Ruth was most closely allied, was SSAR. The 1983 SSAR/HL meeting in Salt Lake City, Utah, was the first national herpetological meeting Ruth attended, and this was to become the main meeting she subsequently would look forward to attending with great excitement.

Ruth Barnes Mull was born in Philadelphia on 2 June 1941, the only daughter and second child of John Barnes Mull of Philipsburg, Pennsylvania, and Helen Carlin of Philadelphia. Ruth is survived by her mother, four children, two grandchildren, her brother, sister-in-law, and six nieces and nephews. Following a memorial service, a reception was held in the Library of The Academy of Natural Sciences of Philadelphia, attended by a large number of Ruth's friends and colleagues. The reception was a fitting tribute to Ruth who was tremendously committed to the Academy. For years she volunteered her considerable intellect and organizational skills to support the Academy's scientific and educational missions.

After attending high school at Notre Dame Academy in Philadelphia from the first grade through her graduation in 1958, Ruth enrolled at Rosemont College, outside Philadelphia, and at Catholic University in Washington, D.C., majoring in drama. In 1960, when she was nineteen years old, Ruth married an ethno-

Ruth M. Zantzinger
1941–1991

graphic film-maker, and over the next several years she traveled to many countries in Asia and Africa on filming excursions. During one of these trips, Ruth's first-born daughter was taken fatally ill and was interred in Malaysia. Following her divorce in 1977, Ruth raised her four additional children, born between 1963 and 1970, in a rural house in Chester County, southeastern Pennsylvania.

Ruth was a master at working with people in a number of civic and service organizations. In 1990, she was elected Chairperson of the Womens' Committee of The Academy of Natural Sciences, and she effectively gave it leadership and coordinated its large membership. The Womens' Committee is an active organization of women volunteers that plans and sponsors a number of fund-raising events on behalf of the Academy's scientific programs. In Philadelphia, one of the largest and most successful of the annual events put on by the Womens' Committee is "Super Sunday," a day-long street fair held in October along the beautiful Benjamin Franklin Parkway and which the *New York Times* in the late 1970s described as "the nation's biggest block party." In 1991, as she had for several years since 1982, Ruth led the planning committee for "Super Sunday" and was instrumental in conducting the business negotiations that made it a success, both for the people of all racial and ethnic groups that attended and the City of Philadelphia, and for The Academy of Natural Sciences.

Another of Ruth's dedications was her volunteer work at the Zoological Society of Philadelphia. Her membership in the Docent Council, where she conducted many guided tours of the Philadelphia Zoo for the public, made her well versed in the natural history and behavior of vertebrates. In recent years, she devised training classes on the biology of amphibians and reptiles for new docents at the zoo. In late October 1991 Ruth received a rarely-awarded commendation by her peers for outstanding service to the Docent Council and to the Zoo. Each Saturday since 1981, whenever she could squeeze in a few hours during times when staff were not in evidence and she could work uninterrupted, she made entries into the animal ledgers. These large books contain historical data on every specimen of every species that became a part of the Philadelphia Zoo's animal collection from around 1874 to the present, and the modern ledgers are used to report pedigree data for global management. Ruth continued a long tradition by restoring beautiful handwriting to the ledgers, but more importantly she made many taxonomic and indexing revisions to them.

Within SSAR, Ruth served as a member of the Zoo Liaison Committee for several years. She presented the results of her survey of zoo snakebite procedures on behalf of the committee at the Missouri meeting in 1986. For the past three years she held the position of Elector, a presidential appointment. She showed eagerness and dedication in her committee work and in voluntarily attending many of the annual Board of Directors' meetings, a classic example of the society's openness in welcoming contributions from the full breadth of its membership. Although she did not have the usual academic credentials that would be considered the norm for entry to positions of responsibility in a scientific society, SSAR later entrusted her with the very heart of its democratic traditions in appointing her as Elector.

A straightforward and honest person, Ruth quickly won the affections of many who would become her most loyal friends. Half amused by this quality in herself, and somewhat proudly complaining of it, when her young nephew and his friend brought home some spring salamanders they had caught in a small stream and the boys begged Ruth to go salamander hunting with them, she said *"Why is it that 14-year old boys are always wanting me to go out in the woods with them? It's been like that all my life!"* Indeed, Ruth had the rare quality of being able to establish a close rapport with nearly everyone whom she respected, young and old alike.

Ruth especially looked forward to SSAR's annual meeting in August of each year. Her contribution to the Society's auction was her most public activity, yet the word 'auction' does not begin to convey the great social extravaganza that these events have become at the annual meetings. As the co-organizer with the auctioneer, Ruth was an elegant hostess, unafraid to take charge in the limelight. She purposely dressed beautifully and was attractively visible to the large gathering of assembled herpetologists. Far beyond her public visibility, however, she devoted much time to pre-selecting the order of items, assisting in displaying them, and, with her typical good humor, elevating the auction to an EVENT. Ruth frequently prepared little prompt cards for various items to be auctioned, and her rapport with the auctioneer was such that she often had only to write a single word on the card to clue Joe Collins as to how best to extract money from the somewhat besotted and pliable audience. Her suggestions (e.g., using credit cards, relegating small duplicate items to a "silent auction," having plenty of beer flowing throughout the evening) accounted in no small way for its technical improvements as well as its success as a major fund-raising event for the Society.

Completing yet another important project for the herpetological community, in 1987 Ruth began compiling an index to the international quarterly publication, *Herpetological Review*. This task, begun innocently enough with her co-author George Pisani, was to consume much of her "spare" time over four years. The publication, *General Index to Herpetological Review*, will be published in 1992. Her work on the *Index* was to her an adventure in which she could learn while performing a useful task in a field she loved. The meticulous nature of the work soon became all too apparent, and as Ruth eschewed computers she carefully hand-typed all records on some 3500 index cards.

Ruth Barnes Mull Zantzinger is loved deeply by her family members and many close friends, and we miss her dearly. Her loss has been devastating in its untimely prematurity. She is irreplaceable. Ruth was warm and joyous, and had a wonderful sense of humor. Who could not recall Ruth's hearty laughter whenever an irreverent comment might have been made by a speaker, and later that same unmistakable laugh as she mingled through the crowd at the evening social functions? Her generosity was appreciated by those to whom she gave her level-headed and candid analyses, donations of material goods, or even financial assistance, in some cases. In mid-October 1991, just weeks before her passing, she displayed her inner strength and her realistic, direct approach to her illness when she wrote: *"I am very much at peace with all of this. I have had a life full of everything and find very few days without some small treasure in them. My regrets are few and I certainly don't feel cheated in any way."* Ruth's deep sense of loyalty to others, her caring about people and about what they did, and her remarkable courage through her final illness serve as model guideposts for our own lives.

NEWSNOTES

Charles Stearns Grants-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology has established a program that provides limited financial aid to graduate students who wish to visit our collections to support their research in systematics.

Proposals should include a short—no more than one page—description of the research project, as well as a letter of support from the student's faculty advisor.

For this fiscal year only, proposals will be due on 15 April, 1992, and grantees will be notified by 15 May, 1992. Grantees will be expected to complete their Academy visit by 15 September, 1992. Proposals submitted for ensuing academic years will be due on 15 October, with notification by 1 December.

Send proposals to:

Herpetology Research Grants
Department of Herpetology
California Academy of Sciences
Golden Gate Park
San Francisco, California 94118-4599, USA
Tel. (415) 750-7037.

Request for Assistance

We are investigating the genetics of threatened populations of black rat snakes (*Elaphe o. obsoleta*) and eastern massasauga rattlesnakes (*Sistrurus c. catenatus*) in Ontario in order to develop appropriate genetic management strategies. Our findings will be of direct value to resource managers and conservation biologists concerned with recovery or protection of these species.

For comparative purposes we require blood samples from populations located outside Ontario. We wish to hear from persons able to assist us in the field collection of blood or identification of local populations. For further information please contact:

Kent Prior
Department of Biology
Carleton University
Ottawa, Ontario K1S 5B6 Canada
Tel. (613) 788-2600 ext. 3862
(613) 230 5991.

MEETINGS

Turtle and Tortoise Symposium

The New York Turtle & Tortoise Society will sponsor the Second International Symposium on Turtles & Tortoises: Conservation and Management, to be held in August 1992.

The three-day event will include lectures and workshops by turtle scientists, conservationists, zookeepers, and veterinarians from all over the world. There will also be a room for vendors.

For further information, contact the Society at (212) 459-4803 or write to 163 Amsterdam Avenue, Suite 365, New York, New York 10023, USA. All persons requesting information on the Symposium will be put on a special mailing list to be notified when details are final.

II Congreso Luso-Español y VI Congreso Español de Herpetologia

The Second Portuguese and Spanish Meeting and the Sixth Spanish Meeting on Herpetology will be held in the city of Granada (southern Spain) 24-27 September 1992, under the auspices of the Spanish Herpetological Society (A.H.E.). It will include plenary lectures, posters, and working groups concerning amphibians and reptiles, mainly of the western Mediterranean area.

On the final day, a full-day excursion will be arranged to the Sierra Nevada Natural Reserve. We may travel by four-wheel drive vehicles, climbing to more than 3,000 m above sea level.

We will welcome anyone working on or interested in Iberian and Mediterranean herptiles. Persons interested in making paper or poster presentations should correspond with the organizing committee by 30 March 1992. Please send your name, address, institution, type of presentation (oral and/or poster) and title(s) to:

Dr. J. M. Pleguezuelos (Organizing Committee)
Departamento de Biología Animal
Facultad de Ciencias
Universidad de Granada
18071 Granada, Spain
FAX: 34-58-243238.

15th Annual All Florida Herpetology Conference

The All Florida Herpetology Conference will be held on 18 April 1992 on the campus of the University of Florida at Reitz Union Auditorium. The Conference is cosponsored by the Florida Museum of Natural History and the Gainesville Herpetological Society. Speakers include David Chiszar (University of Colorado, Boulder), James Gillingham (Central Michigan University, Mt. Pleasant), William Haast (Punta Gorda, Florida), Dale Marcellini (National Zoological Park), Sherman A. Minton, Jr. (Indiana University Medical Center, Indianapolis), Edward Moll (Eastern Illinois University), Ron Tremper (Reptile Breeding Center, Inc., Fresno, California), Trooper Walsh (National Zoological Park), and Peer Zwart (University of Utrecht, The Netherlands).

Other events include a panel discussion, exhibition and sale of herpetological books, art, etc., a workshop for young herpetologists, and an evening barbeque and auction at the Florida Museum of Natural History. For registration material or additional information, contact:

David Auth
Division of Herpetology
Florida Museum of Natural History
University of Florida
Gainesville, Florida 32611, USA
Tel. (904) 392-1721.

Symposium on Eastern Massasauga

Metro Toronto Zoo is hosting a two day International Symposium and Workshop on the Conservation of the Eastern Massasauga Rattlesnake, 8-9 May 1992. Papers on conservation, status, and field research will be presented from all states and provinces within the range of this threatened species. Keynote speaker will be a European researcher who will provide an update on similar conservation programs for viperids in Europe. A post conference

trip to view *Sistrurus catenatus catenatus* in the wild is planned. The workshop will address the international conservation efforts required to protect populations throughout the range in Canada and the U.S.

Papers are solicited. For further information contact Bob Johnson, Curator of Amphibians & Reptiles, Metro Toronto Zoo, P.O. Box 280, West Hill, Ontario, Canada M1E 4R5, Tel. (416) 392-5968, FAX (416) 392-4979.

REGIONAL SOCIETIES

International Iguana Society

The International Iguana Society (IGS), a non-profit corporation filed with the Secretary of State of Florida, is dedicated to the preservation of the biological diversity of iguanas. Many species of iguanas are in immediate danger of extinction, especially the West Indian rock iguanas of the genus *Cyclura*. IGS believes that the best way to protect iguanas and other native faunas and floras is to preserve natural habitats and encourage the development of sustainable economies, i.e., those compatible with the maintenance of biodiversity. IGS hopes to influence and help governments and agencies to protect the unique natural heritage of the West Indian region before it is lost. They also hope to garner the support of other conservation groups and the scientific community to accomplish their mission. IGS encourages the dissemination and exchange of information of all aspects of the ecology, population biology, behavior, captive husbandry, taxonomy, and evolution of iguanas.

Membership dues are $25 US Regular and $30 US Organizational. Dues support active conservation projects and members receive a subscription to the *Iguana Times*, a quarterly newsletter. Those interested in joining IGS or receiving information about the group should contact:

International Iguana Society
Finca Cyclura
Route 3, Box 328
Big Pine Key, Florida 33043, USA
Tel. (305) 872-9811.

LEGISLATION & CONSERVATION ALERT

This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered herps. We are in need of more information, especially at state and regional levels. Please send pertinent information to the Section Editor.

The following final and/or proposed listings, regulations, and general information have been announced by governmental regulatory agencies. Pertinent Federal Register (FR) citations are given for U.S. notices.

USA, Virginia: *Crotalus horridus atricaudatus* (canebrake rattlesnake). On 1 January 1992, the Virginia Department of Game and Inland Fisheries (VDGIF) listed the subspecies as Endangered. *Clemmys insculpta* (wood turtle), *Ophisaurus ventralis* (eastern glass lizard), *Ambystoma mabeei* (Mabee's salamander), and *Hyla gratiosa* (barking treefrog) were listed as Threatened by VDGIF on 1 January 1992. All five threatened species have restricted geographical ranges within Virginia and all are suffering reductions in populations and loss of habitat due to development. For further information contact the Virginia Department of Game and Inland Fisheries, 4010 West Broad Street, Richmond, Virginia 23230, USA.

USA: *Clemmys marmorata* (western pond turtle) and *Rana aurora draytoni* (California red-legged frog). The U.S. Fish and Wildlife Service, Region 1, Portland, Oregon has been sent a petition from Dan C. Holland, Mark R. Jennings, and Marc P. Hayes to list *R. aurora draytoni* as federally Endangered throughout its range and *C. marmorata* as federally Endangered in Washington, Nevada, Oregon (Columbia, Willamette, and Klamath drainages), and California (Klamath River downstream to confluence with Scott River, Clear Lake drainages, Central Valley drainages from Mokelumne River south, Mojave River and all desert drainages, and all southern California drainages including the Santa Clara River and south), and as federally Threatened in Oregon (Umpqua, Rogue, and coastal drainages) and California (Klamath River from downstream of Scott River confluence, all north coast drainages, Central Valley drainages from Mokelumne River north, all non-Central Valley drainages from San Francisco Bay south to Santa Clara River). For further information contact: Dan C. Holland, 2310 Alturas, Bakersfield, California 93305, USA.

USA: *Conraua goliath* (goliath frog). The U.S. Fish and Wildlife Service proposes to determine Threatened status for the goliath frog of Central Africa. This amphibian is rare and narrowly distributed, and is threatened by habitat loss, commercial trade, and local hunting. If listed, permits would be available to enhance propagation or survival of the species and for scientific purposes that are consistent with the purposes of the Endangered Species Act of 1973 (FR 56, no. 177, 12 September 1991, pp. 46397-46400).

Japan: *Eretmochelys imbricata* (hawksbill sea turtle). Japan has agreed to end all hawksbill imports by 31 December 1992, and to sharply reduce its imports until that time (Endangered Species Tech. Bull. 16, nos. 7-8, July/August 1991).

USA: The U. S. Fish and Wildlife Service has produced an updated compilation of amphibian and reptile taxa native to the United States that are being reviewed for possible addition to the List of Endangered and Threatened Wildlife under the ESA (FR 56, no. 225, 21 November 1991, pp. 58804-58836). In revising this compilation the USFWS relied on information from status surveys, State Natural Heritage Programs, other State and Federal agencies, knowledgable scientists, and comments received in response to previous notices of review. Taxa are assigned to one of several categories. For example, C1 = taxa for which there is substantial information on biological vulnerability and threats to support proposals to list them as Threatened or Endangered; C2 = taxa for which information indicates that proposing to list them as Threatened or Endangered is probably appropriate; 3C = taxa that have proven more abundant or widespread than previously believed, but may be re-evaluated for C1 or C2 status if declines are documented; 3A = taxa for which the USFWS has persuasive evidence of extinction.

TABLE 1. Number of species and subspecies of amphibians and reptiles native to the U.S. that are being reviewed for possible addition to the List of Endangered and Threatened Wildlife under the Endangered Species Act of 1973.

	C1	C2	3C	3A
Salamanders	2	35	1	0
Anurans	3	20	0	2
Lizards	1	24	0	0
Turtles	1	12	0	0
Snakes	3	29	0	0
TOTAL	10	120	1	2

Grand Total = 133 taxa

The SSAR Conservation Committee strongly urges those herpetologists with conservation interests to obtain a copy of the above mentioned Federal Register and scan it for taxa of interest. The USFWS hopes that their review notice will encourage necessary research on vulnerability, taxonomy, and/or threats for these taxa. Federal Register vol. 54, 6 January 1989, pp. 554-579 contained the previous review of this list.

KURT A. BUHLMANN
SSAR Conservation Committee.

Gopher Tortoise Council Initiates Upland Habitat Protection Project

The Gopher Tortoise Council, a conservation organization based in the southeastern United States, has launched an effort to protect the Southeast's rapidly disappearing xeric upland habitats. Host to an array of uniquely adapted reptilian, mammalian, and avian faunas and floras, these dry, well-drained sandy habitats are sought equally by development, agriculture, forestry, and mining interests. Although the Council's activities focus on the gopher tortoise, the organization's goal is to preserve the entire spectrum of plants and animals—from scrub morning glories to fox squirrels and indigo snakes—in these native upland communities.

Gopher tortoises belong to a group of land tortoises that originated almost 60 million years ago in North America. Of the 23 species that once existed on our continent, only four are alive today; the gopher tortoise (*Gopherus polyphemus*) is the only species found in the eastern United States. Gopher tortoise populations are scattered throughout the southeastern coastal plain from South Carolina to Florida and west to Mississippi. The highest concentrations are located in north-central Florida and southern Georgia. Gopher tortoises have been greatly reduced throughout their range; in Florida alone populations have dwindled to an estimated 30% of their historical levels.

The burrow system of the gopher tortoise provides refuge to more than 360 other species of animals. For this reason, the gopher tortoise has been designated as a keystone species in upland communities. Other reptilian species such as the eastern indigo snake (*Drymarchon corais couperi*), gopher frog (*Rana areolata*), and short-tailed snake (*Stilosoma extenuatum*) are on state and federal threatened or endangered species lists due to severe declines in their numbers, resulting from destruction of their habitat. Although a decade of effort by the Council has given the gopher tortoise legal protection in the six states in which it occurs, neither federal nor state laws protect the habitat on which the tortoise and hundreds of other species depend for survival. The delusion that legal protection of animals implies species preservation is epitomized by continued decline of tortoise populations.

In the face of this threat, the Council has created the Upland Habitat Protection Project (UHPP), the only land conservation effort which specifically targets uplands. The central focus of the UHPP is to identify and monitor specific upland sites most in need of preservation. The UHPP will coordinate a region-wide inventory effort that will culminate in the production of a list of priority sites in need of protection. The Council will prepare proposals to submit to agencies and organizations which have funds earmarked for environmental land acquisition. In Florida alone, more than $600 million per year are potentially available for this. The Council will work closely with state natural heritage programs, governmental agencies, academic institutions, and private individuals to provide a comprehensive review and analysis of existing information, which will be supplemented by focused field investigations.

GTC is seeking additional contributions in any amount from individuals and organizations. These funds will subsequently be used to solicit matching funds from appropriate agencies. Tax-deductible donations may be sent to the Gopher Tortoise Council c/o 1018 Thomasville Rd. Suite 200-C, Tallahassee, Florida 32303, USA. For additional information or a copy of GTC's brochure, contact Leslie HaySmith at the above address (tel. 904/224-8207).

ARTICLES

Intraspecific Oophagy in Stream-breeding California Newts (*Taricha torosa*)

The jelly coat on the egg mass of many aquatic breeding salamanders is thought to protect developing embryos from predation (Semlitsch 1988, Ward and Sexton 1981). In addition to having a firm jelly coat, eggs of California newts (*Taricha torosa*) are believed to be unpalatable to many predators because they contain a potent toxin (Buchwald et al. 1964, Mosher et al. 1964). Two studies have shown that pond-breeding adult California newts will cannibalize newly deposited egg masses (Kaplan and Sherman 1980, Marshall et al. 1990). While studying the microsite (runs, riffles, or pools) oviposition preferences of female newts in a California stream, we documented oophagy by adult newts over a five week period.

Our study site is a first order stream in the Santa Monica Mountains (Los Angeles Co., California). This is a fishless, perennial stream. We began weekly surveys of a 1.5 km stretch of the stream for adults and egg masses on 25 March 1991. Breeding adults were observed on the first week in April and egg masses were present by the second week in April. No new egg masses were observed after 25 April. Although the stream consisted of runs, riffles, and pools, most oviposition occurred in stream pools (unpublished data). We carefully counted the number of egg masses in seven stream pools between 1 and 10 May and compared these data to the number of masses present in the same pools five weeks later (masses counted between 10-12 June) just as larvae were hatching. A few larvae had hatched from some masses. Pools were small (generally $<10 m^2$). Adults and egg masses were relatively easy to observe and count. On 11 visits to the stream between 1 May and 21 June we recorded and observed

all oophagic events. In addition, we used water lavage to examine the stomach contents of 15 adult newts between 6 and 17 June.

We observed adult newts feeding on newt egg masses on five occasions. We observed one adult preying on egg masses on 8 May, 6 June, and 10 June. On 18 June six adults were observed in a pool and three of the six were observed eating eggs. On 21 June nine adults were observed in a stream pool and four individuals consumed egg masses. All masses being eaten contained embryos and all embryos were Harrison stage 38 or older. Between 6 June and 17 June, we flushed the stomachs of 15 adult newts and found newt embryos or egg mass remnants in six of them. Sexes of the animals were difficult to determine since by this time of the year adults had lost their conspicuous secondary sex characteristics. We elected not to sacrifice any animals for sex determination.

We found a significant reduction in the number of egg masses present in the seven stream pools between May and June (paired t-test, t=3.46, P=0.013, df=6; Table 1). Although hatching had begun in some egg masses there were no empty egg masses (where hatching was complete) found in the June survey even in sections of the stream that did not contain adult newts. Thus, all masses consumed by the adults likely contained embryos.

The significant reduction in egg masses in stream pools was likely caused by oophagic adults. In over 40 different visits to the stream pools in the spring and summer no other egg mass predators were observed in the stream. *T. torosa* egg mass jelly is very firm and appears to be quite resistant to predation by stream invertebrates (unpublished data). Invertebrates in this stream are capable of damaging the egg masses, but there is no indication that they are capable of completely removing egg masses. Stream current in May and June was 20-25 l/min and was incapable of dislodging attached egg masses or even relocating the few masses that were unattached.

TABLE 1. A comparison of the number of California newt egg masses present in stream pools in May, 1991 and five weeks later.

Pool #	# masses in May	# masses in June
1	30	13
2	5	2
3	43	30
4	50	20
5	5	0
6	7	1
7	45	34

Although oophagy is apparently not rare in amphibians (see for example Baldauf 1947, Marshall et al. 1990, Wood and Clarke 1955), previous observations on pond-breeding *T. torosa* noted that oophagy only occurred within a few hours after oviposition and before egg mass jelly hardened (Kaplan and Sherman 1980, Marshall et al. 1990). In addition, adults typically leave the aquatic habitat soon after breeding (Stebbins 1972). In our stream system, adults stayed in the stream long after breeding and oophagy occurred throughout the developmental period. Egg masses were still being consumed six to seven weeks after oviposition. Our direct observations of oophagy revealed that adults are very persistent in ripping off pieces of egg mass. Adult newts were observed biting egg masses and then completely twisting their bodies in attempts to tear off portions of the masses.

Given that cannibalism was observed in 45% of the visits to the stream (5 occasions out of 11 visits) and stomach flushes produced remnants of egg masses or larvae 40% of the time, we feel that cannibalism is a strong selective force on this population of California newts. In subsequent years we will investigate variation between adult tendencies to cannibalize and whether oophagic adults can discriminate between their own eggs and eggs that are unrelated. Since causes of cannibalism are often uncertain or varied (Polis and Myers 1985), we plan to continue tracking potential changes in the intensity of cannibalism with each breeding season.

Acknowledgments.—This research was supported by grants from the Pepperdine University Council and NSF REU-BSR-9100731. We appreciate the logistic support of Jo Kitz and the Mountains Restoration Trust. Brad Staehle and Nathan Van Rheenen helped in some of the field work.

Observations on the Tolerance to Freezing by the Lizard, *Sceloporus grammicus*, from Iztaccihuatl Volcano, México

Five species of vertebrates (four anurans and one turtle) are known to tolerate intercellular freezing during winter by producing cryoprotectant chemicals (Storey and Storey 1988, Storey et al. 1988). Recently, freeze tolerance was reported in the lizard,

Podarcis muralis (Claussen et al. 1990). We provide preliminary observations on the freeze tolerance in a high altitude lizard, *Sceloporus grammicus* from the slopes of Iztaccihuatl Volcano on the border between the states of Puebla and México, México.

On 29 June 1991, seven adult specimens of *Sceloporus grammicus* (collected at 3600 m in the Campo Experimental Forestal de San Juan Tetla, Puebla, 17 km W of San Felipe Teotlatzingo) and seven specimens (one juvenile and six adults) of *S. mucronatus* (from 3000 m altitude from KM 41 on Mex. Hwy. 15, Edo. de México) were placed in a home freezer (ca. 0°C) to kill them prior to preservation. The following day (after 28 h) the specimens were removed from the freezer. They appeared solidly frozen, some ice was evident on the external body scales, but after approximately one half hour of warming at room temperature (25°C), movement was noticed among the *Sceloporus grammicus*. After thawing completely, all seven *S. grammicus* were alive and active whereas all *S. mucronatus* were dead.

Additional preliminary experiments were conducted with *S. grammicus* to substantiate these field observations. Specimens from the Iztaccihuatl Volcano location were collected (14 August 1991) and transported to Lincoln, Nebraska. On 6 September 1991, four *S. grammicus* (two adult males, 52 and 55 mm SVL, and two adult females, 47 and 49 mm SVL) were placed in a freezer at -2.5°C for 37 h. These specimens were checked periodically during this time and all appeared to have frozen solidly within a few hours. Upon removal from the freezer, these lizards warmed rapidly (5-10 min) while being held, and all survived. Three additional specimens (two adult males and one adult female) were placed in a freezer at -6.5°C until solidly frozen. After 3 h these specimens were removed from the freezer to thaw; none survived. On 27 October, after approximately ten weeks in captivity, two of the above males were placed in a freezer at -1.7°C and survived for 32 h and then at -2.3°C; these two survived to 6 h but were dead at 20 h.

These observations are consistent with the general phenomenon of freeze tolerance reported in vertebrates (Storey et al. 1988). *Sceloporus grammicus* naturally encounters freezing temperatures frequently during the year. We recorded (with max-min thermometers) temperatures as low as -3°C in the summer of 1991 at a high altitude site of 4400 m on Iztaccihuatl Volcano where population studies are underway. Temperatures of 0°C were recorded twice at 3600 m where the above specimens were collected between late May and late August (typically the hottest months of the year). Because *Sceloporus grammicus* may be exposed to frequent low temperatures its tolerance to freezing is not surprising.

Acknowledgments.—We thank C. Gonzalez-Vicente of INIFAP-SARH of México for providing assistance during our field studies. A permit (412.2.1.2.0.06869 Direccion General de Conservacion Ecologica de los Recursos Naturales) to collect specimens for research was kindly granted by Dr. Graciela de la Garza Garcia. Lab research was conducted under UNL IACUC #89-03-009. We thank K. Storey for advice, and J. Rowe and G. Smith for reading an initial draft of the manuscript.

POINTS OF VIEW

Commentary on a Proposed Taxonomic Arrangement for Some North American Amphibians and Reptiles

Collins (1991) believes that a relatively large number of North American species of amphibians and reptiles are camouflaged by the subspecies taxonomy currently in use. He considers this taxonomic concept out-dated, and presents a list of 55 allopatric subspecies which he proposes should be elevated to the rank of full species. My purpose here is to comment and take issue with some of the views expressed in his paper.

Collins offers no explanation or supporting evidence for his contention that the subspecies concept is outdated. In fact, there is little evidence to suggest that this is so. Subspecies are used in all major field guides for reptiles and amphibians, and new subspecies continue to be named and described in the primary literature. There is no doubt that the concept has been abused, that cases of character discordance, polytopic characters, and smooth clinal variation have limited its application (Wilson and Brown 1953), and that some subspecies are, in fact, good "biological" or evolutionary species. Despite such problems, the concept retains its usefulness in taxonomic practice (Mayr 1982).

The subspecies concept persists for theoretical reasons as well. The allopatric speciation model (models I and II of Wiley 1981) explains, by far, the majority of recognized species. The formation of geographical races (subspecies) is considered to be a common early stage in the speciation process, and the pervasiveness of geographical variation supports this theory. An extensive literature documents geographical variation in the vast majority of vertebrate and invertebrate species. These variational patterns, in most cases, lend themselves to the recognition of geographical subdivisions. Although recent revisionary studies of the herpetofauna have shown some widespread, polytypic species to consist really of several evolutionary or "biological" species (see Frost and Hillis 1990, for cases), this does not invalidate the theoretical concept of how these species arose.

Collins refers to his listed taxa as "camouflaged" or "hidden" species, but these terms are misleading, implying that the taxa are somehow lost and unavailable for study. On the contrary, the Latinized trinomial calls attention to the fact that the taxon is considered distinctive in some way. Publication of the subspecific name with designation of type and paratype material ensures that the taxon remains available for systematic reassessment. Use of the trinomen in any information storage and retrieval system ensures the accessibility of such taxa for various studies, e.g., faunal surveys, biodiversity studies, and listings of endangered and threatened taxa.

Collins is critical of the taxonomy in use by herpetologists today, calling it arbitrary and lacking historical reality. But, in my opinion, his proposed taxonomic arrangement is no less arbitrary than the existing taxonomy. The specific status of his listed taxa is "revealed," he claims, by their allopatric distributions and morphological distinctness. Several points need to be made concerning allopatry. Some of his listed taxa are separated by tremendous distances, but others show varying degrees of prox-

imity, and in some cases, the hiatus may be an artifact of collecting effort, not biological reality. The absence of records in the distributional gap by no means confirms the absence of populations there. Furthermore, the distributional boundaries of species are not static, but exceedingly dynamic (MacArthur 1972). The existence of peripheral isolates, far removed from the main distribution of a species, is evidence of profound changes in the range boundaries having occurred during the past. Etheridge (1958), Holman (1977), and others cite examples of distributional changes in the North American herpetofauna since the Pleistocene. The condition of allopatry, therefore, does not preclude the possibility, or even the likelihood, of interactions occurring through time.

In reviewing the diagnostic comparisons between listed forms and the nominate taxa of the species, I find considerable variation in the level of morphological distinctness. In some cases, the allopatric taxa differ strongly by a single, conservative character, or combination of traits (e.g., morphology, color pattern, behavior), so that identification is possible 100 percent of the time or nearly so (e.g., *Scaphiopus h. holbrookii* and *S. h. hurterii*). At the other extreme, the differentiation is patently trivial, involving mean values of meristic characters that overlap considerably and which are not likely to meet the accepted level of statistical significance. In other cases, slight differences in color pattern are noted between populations that show considerable individual variation, dorsal pattern polymorphism, and/or ontogenetic variation (e.g., *Masticophis b. bilineatus* and *M. b. lineolatus*; *Eumeces g. gilberti* and *E. g. arizonensis*). Approximately 32 to 38 of the 55 taxa listed by Collins are, in my judgement, weakly differentiated.

Frost and Hillis (1990:93) caution "As a practical matter, no one wants to name weakly differentiated or undifferentiated allopatric populations if there is no phylogenetic reason . . . to do so. In fact, to start down this path is to end up imposing the 'phylogenetic' species concept with its possible over-reductionism." Unfortunately, I believe this is the path Collins is taking. Considering the highly dynamic property of organismal distributions, and the modest levels of differentiation exhibited by many of these allopatric taxa, it is reasonable to assume that most are interacting or likely to interact with other members of the binomial taxon, and are therefore conspecific. The burden of "proof" that these allopatric taxa are distinct evolutionary species rests with the advocates. Smith (1990) noted that the evolutionary species concept championed by Frost and Hillis (op. cit.) requires certain standards to justify the assumption of attainment of an independent evolutionary trajectory. He proposed as a suitable standard for allopatric populations 100 percent recognizability by some character or suite of characters. Few of the taxa listed by Collins meet this standard.

I believe that it is inappropriate for Collins to encourage the herpetological community to accept his proposed taxonomic arrangement in toto. Some of the listed taxa have been named and described in a piecemeal fashion, while others have been described following the study of geographical variation and phylogenetic analysis. In my opinion, the only reasonable position on this matter is to review these taxa on a case by case basis. Reassessment is a normal part of systematics, and systematists should do the job using all the technology now available. While I support the rigorous application of the evolutionary species concept, I would rather wait for specialists to evaluate these taxa tomorrow than commit taxonomic mayhem today.

Viewpoint: Reconsider Suggested Systematic Arrangements For Some North American Amphibians and Reptiles

Collins (1991) recently proposed that 55 allopatric, morphologically distinct subspecies of amphibians and reptiles be raised to species rank because "a relatively large number of species . . . have been camouflaged by the 'subspecies' taxonomy that I think is an outdated viewpoint." Apparently, field or museum specimens were not examined and changes were based on distribution maps and current subspecific status. Responding to Collins' taxonomic proposals necessarily involves discussion of concepts, methods, and assumptions that cannot be addressed here in full. Here we discuss various aspects including (1) unsubstantiated taxonomic changes based primarily on our knowledge of the animals, and the literature, (2) the significance of geographic isolation as a criterion for recognizing species, (3) the antiquity of species and subspecies, and (4) the validity and importance for taxonomy of several assumptions in cladistic analysis.

Collins' "outdated viewpoint" is the Biological Species Concept (BSC)—species are groups of actually or potentially interbreeding natural populations reproductively isolated from other such groups (Mayr 1942, 1963, and elsewhere). The "actually or potentially" is often left out by BSC critics; the allopatric populations in Collins (1991) are, of course, potentially interbreeding populations. Simpson (1961) defined the species in the Evolutionary Species Concept (ESC) as "an ancestral-descendent sequence of populations evolving separately from others and with its own unitary role and tendencies." His ESC species are BSC species moving through time. For cladistic purposes Wiley (1981) embraced the ESC and would restrict its application to populations defined by "recovered historical relationships"—i.e., cladistic analyses of morphological characters. Collins (1991) stated that "a rigorous application of the evolutionary species concept (as discussed in Frost and Hillis 1990) would also reduce the number of arbitrarily defined subspecies dramatically." Frost and Hillis (1990) state that "intelligent use of trinomials could only follow phylogenetic analyses; otherwise their application in alpha taxonomy would be precluded." A cladistic analysis of

characters is claimed necessary to recognize subspecies, but not to elevate them to species.

Collins' proposed taxonomic changes reflect populations that have been isolated for different lengths of time and have varying degrees of morphological differentiation. He raised the western subspecies, *mormon*, of the widespread polytypic *Coluber constrictor* to a species, apparently following Fitch et al. (1981). However subsequent papers by Greene (1984) and Corn and Bury (1986) provided evidence for intergradation in New Mexico and western Texas south of the Rocky Mountains, and in Colorado, Wyoming, and Utah to the north. They concluded that the elevation of *mormon* to species status was not supported by morphological, reproductive, or zoogeographical evidence. If the predicted global warming of 2°C mean annual temperature by 2000 comes to pass, the intermediate relict populations could well disappear, qualifying the newly isolated *mormon* as a species only under Collins' system. There is no reason to think that widespread subspecies such as *mormon* or *flaviventris* will acquire new characters through natural selection in response to such a climate change or to being separated from each other. In this case, range fragmentation would not be coupled with evolutionary change.

The subspecies of *Tantilla rubra* (*cucullata* and *diabola*) in the United States were elevated to species rank. Degenhardt et al. (1976) have already reported an intermediate population in the Chisos Mountains of Big Bend National Park with the distinctive nuchal collar absent (*cucullata*), complete (*diabola*) or partially present. The intergrade zone actually covers much of the Big Bend from Black Gap to Terlingua (H. K. McCrystal, unpubl. data). With further collecting, the Trans-Pecos populations of these secretive snakes will undoubtedly prove to be continuous, as desertscrub populations tend to be. Using Collins' criteria, would the Big Bend population with characters of both *cucullata* and *diabola* warrant full species status? In contrast, we suspect that if enough specimens were available to assess geographic variation, only a single subspecies would be recognized in Texas.

Collins (1990) and Conant and Collins (1991) followed Gartska (1982) in elevating *Lampropeltis mexicana alterna* to a species using characters (iris color, head shape) that could as well reflect infraspecific adaptive responses (subterranean crevice dwelling, nocturnal activity) to the Chihuahuan Desert. In this case, *alterna* freely interbreeds in captivity with other *L. mexicana* subspecies but not sympatric *L. triangulum*. The presence of alternating reduced markings in Gartska's captive-bred offspring of *L. m. thayeri* from Nuevo Leon could be interpreted as gene flow from *alterna* rather than invalidating the use of color pattern in recognizing subspecies. Gelbach and McCoy (1965) reported *alterna* x *mexicana* (including *greeri*) intergrades from Durango. Collecting bias cannot be neglected when discussing secretive, widely distributed polymorphic taxa; intergrades between *alterna* and *thayeri* were subsequently found in southeastern Coahuila (S. F. Hale, pers. comm. 1989). Would Collins' "species" revert to "subspecies" when intermediate specimens are found in intervening areas?

Lampropeltis pyromelana infralabialis, the subspecies isolated north of the Grand Canyon in Arizona, Nevada, and Utah, is a barely distinguishable population raised to species by Collins. Tanner's (1953) description separated *infralabialis* from other subspecies on one less infralabial scale and white annuli complete across the ventrals in 50% or more of the body annuli. A careful study of *L. pyromelana* specimens throughout the species' range (independently by W. H. Woodin and C. H. Lowe, unpubl. data) reveals that color pattern is highly variable throughout the range with *knoblochi* and, *infralabialis* more weakly so, the only populations divergent at the subspecific level. The would-be elevation in rank of little-differentiated subspecies (as by Collins, and by Frost and Hillis) dilutes and weakens our understanding of species while only appearing to increase biodiversity. Strangely, according to these authors, subspecies are apparently not included in biodiversity. As Cole (1990) correctly pointed out, overestimating the number of species for ulterior motives including conservation will only injure the image and credibility of systematists. We are impressed only that *infralabialis* differs so little from other *L. pyromelana* after 10,000 yrs of isolation and over 2000 generations in the present interglacial; stabilizing selection is very strong.

The subspecies of *Lampropeltis zonata* raised to species (*multifasciata, parvirubra, pulchra*) in Collins (1991) are examples of slightly differentiated kingsnake populations in isolated mountain ranges with which we are again familiar. An intergrade specimen between *multifasciata* and *zonata* from an intermediate range cited by Zweifel (1952) was overlooked or disregarded, and others are unreported. The extensive fossil record of plants and animals preserved in ancient packrat (*Neotoma* spp.) middens throughout the southwestern United States and northern Mexico have shown that most montane populations have been isolated for about 9000 yrs (Betancourt et al. 1990, Van Devender et al. 1991a). During each of 15 to 20 glacial periods during the Pleistocene, montane woodlands were reconnected in the intervening lowlands. Glacial climates with widespread woodland biotas were the typical situation for perhaps 90% of the last 1.8 million yrs (Imbrie and Imbrie 1979).

Packrat middens have provided records of presently montane reptiles in lowlands in ice age woodlands in Texas: e.g., *Gerrhonotus liocephalus* (Texas alligator lizard) in the Big Bend (Van Devender and Bradley, in press), and *Phrynosoma douglassi* (short-horned horned lizard) near Van Horn (Montanucci 1987). The middens also record montane animals in Arizona ranges where they no longer occur: e.g., *Gerrhonotus kingii* (Arizona alligator lizard) at 29,000, 14,500, and 9570 yrs B.P. (radiocarbon years before 1950) in the Ajo Mountains, and *Tamias* sp. (chipmunk) at 21,840 and 13,500 yrs B.P. in the Ajos, and 12,430 yrs B.P. in the Tucson Mountains (Van Devender et al. 1991b).

Prediction based on clear patterns in data is an integral part of science; a new glacial could begin any millenium unless man alters the earth's climate system too drastically. Would *multifasciata, parvirubra*, and *pulchra* then be reduced to subspecies status again when their ranges reconnect with each other and with *zonata* as they undoubtedly have many times in the past? Reticulate evolution, a common evolutionary mechanism in plants, has occurred in many animal populations currently recognized as subspecies. Cladistics cannot reconstruct the phylogeny of groups with reticulate evolution (Donoghue 1985).

Hundreds, if not thousands, of isolated, slightly and clearly differentiated populations in woodlands and forests on southwestern mountaintops have *not* been described as subspecies or plant varieties. The divergence may have occurred in the last 10,000 yrs or represent the cumulative natural selection of many Pleistocene interglacials. Under the Phylogenetic Species Concept (PSC) proposed by Donoghue (1985) where species are defined on the basis of monophyletic lineages, isolated populations with *any* discernible differences whatever are species (see discussion in Echelle 1990). This dubious definition frees the cladist from making troublesome taxonomic decisions—most infraspecific groups including demes, forms, varieties, subspecies, and semispecies become species. The montane populations noted above would become "species" regardless of how slightly differentiated.

Crotalus lepidus (rock rattlesnake) is widespread in the southwestern United States and much of northern Mexico. Four subspecies have been described (*klauberi, lepidus, maculosus, morulus*) in broad biogeographic regions. In the United States the ranges

of *klauberi* and *lepidus* span 1030 km from Arizona to Texas. A complex mosaic of modestly differentiated populations in various habitats, rock types, and elevations makes rigorous definition of *klauberi* and *lepidus* difficult, raising the question of whether they should be combined (H. K. McCrystal, unpubl. data). Under Wiley's ESC and the PSC, two variable subspecies of *C. lepidus* would be immediately divided into 20 or 30 species in the United States alone with greater geographic than genetic differences! Again, most of the populations have undoubtedly been isolated only 9000 yrs or less and are likely to be reconnected in the future.

In fact, over 400 species of animals and plants have been identified from packrat midden deposits radiocarbon dated 10,000 to 50,000 yrs B.P. Although species were described on obvious distinctive characters such as color pattern and scalation in snakes, or flower and fruit structure in plants, many other structures are usually distinctive. Teeth, bones, scales, heads, elytra, seeds, fruits, leaves, twigs, spines, etc. in middens are readily matched to modern reference specimens with virtually no differences. Even if a few cryptic species were missed, the last major glacial/interglacial climatic change (the Wisconsin/Holocene) did not produce many new species in the southwestern United States. There is little reason to believe that earlier Pleistocene climatic changes were of greater magnitude with more speciation.

The rich fossil record of beetles in Europe (Coope 1991) and the Rocky Mountains (Elias 1991) has challenged the idea that most living species evolved continuously throughout the Pleistocene with rapid speciation during massive environmental perturbations. All insect fossils dating to the last million years are morphologically identical down to details of the genitalia to existing species. Beetles responded to ice age climatic cycles through great shifts in geographical range rather than evolution of new adaptive types or extinction.

Many reptilian subspecies are mostly restricted to major biogeographical regions, e.g., the Great Plains: *Crotalus viridis viridis, Elaphe guttata emoryi, Lampropeltis calligaster calligaster, L. getulus splendida, L. triangulum gentilis, Pituophis melanoleucus sayi*; the Chihuahuan Desert: *Lampropeltis mexicana alterna, Trimorphodon biscutatus vilkinsoni*; mainland Mexico Sonoran Desert: *Masticophis flagellum cingulum*; Baja California Sonoran Desert: *Arizona elegans pacata, M. f. fuliginosus, Pituophis m. bimaris, Salvadora hexalepis klauberi*; Sinaloan thornscrub and tropical deciduous forest: *Lampropeltis g. nigritus, Rhinocheilus lecontei antoni*; Great Basin Desert: *Crotalus v. lutosus, C. v. nuntius, Pituophis m. deserticola*; Mediterranean chaparral: *Crotalus v. cerberus, C. v. helleri, Pituophis m. annectens*. These distributions strongly reflect adaptive responses of species to geologic events and their climatic consequences predating the Pleistocene. The most important geologic events were the uplifts of the Rocky Mountains and the Sierras Madre Occidental and Oriental resulting in regional weather patterns and the modernization of North American biotic provinces—mostly 8 to 20 million years ago in the Miocene (Axelrod 1979).

Pleistocene climates mostly shifted biotic provinces southward with increased species richness under equable climates. Except for tortoises there are very few extinct species of amphibians and reptiles described from the Pleistocene of North America. *Phrynosoma josecitensis*, a problematic species known from a single squamosal bone from late Pleistocene sediments in San Josecito Cave, Nuevo Leon, México, may be an aberrant specimen of a living species (Montanucci 1987). Even in tortoises, species such as *Gopherus flavomarginatus* (Bolson tortoise) may have evolved in the Pliocene at least two million years ago (Bramble 1982). Thus, subspecies in widespread continental species are more likely to be millions of years old than to have formed in response to the most recent glacial/interglacial climatic change. Subspecies are undoubtedly much more stable than their geographic ranges—one of Collins' main criteria for species.

We view modern species as fundamental, stable, long-lived evolutionary entities that usually do not evolve or go extinct in response to environmental fluctuations; most species simply shift their ranges. When speciation in isolated populations does occur, the fate of the parent population (extinction, stasis, speciation) is independent of its descendants' fate, and would rarely, if ever, be coupled as they are in the divaricate branching of shared, derived (apomorphic) characters in cladistic analyses (Wiley 1981). In spite of cladistic assumptions, the temporal coexistence of ancestral species or subspecies in older habitats with their descendants in derived habitats is the normal state of affairs. With the first glacial climates about two million years ago, boreal forests moved almost to the Gulf of Mexico, disrupting the Gulf Circumferential Corridor between the southeastern United States and northeastern México (Auffenberg and Milstead 1965), splitting the range of *Drymarchon corais* (indigo snake). There is no reason to believe that the natural selection that formed the southeastern *D. c. couperi*, elevated to species rank by Collins (1991), had any affect on the parental populations in south Texas or northeastern México. Barring other information, *D. c. erebennus* could be the living ancestor of *couperi*.

The subspecies concept has been very useful in describing patterns of geographic variation within species. While concurring, O'Neill (1982) nevertheless incorrectly viewed Mayr's (1963) definition of a subspecies ("an aggregate of local populations of a species inhabiting a geographic subdivision of the range of the species, and differing taxonomically from other populations of the species") to be that of a taxonomic unit rather than an evolutionary one.

Johnson (1982) argues correctly as has Mayr from 1942 onward that a great deal of information on evolutionary variation in species is already cast in a subspecies framework, and that the names call attention to distinctive populations with significant research potential. Difficulty in delineating subspecies in widespread complex species like *L. triangulum* with 25 subspecies (Williams 1988) would in no way justify the elimination of all subspecies with little if any gain in knowledge. *Lampropeltis* would change from a genus with six species with variable numbers of subspecies to over 50 so-called species!

Actually the naming of populations with discontinuous clinal or allopatric variation inherently expresses inferred relationships. We use the concept of "related" in the traditional sense to mean the degree of genetic similarity between two taxa rather than the limited cladistic redefinition of sharing a derived character (Wiley 1981). Because species are as stable and long-lived as the fossil record indicates, the most closely related species are ancestor and descendent(s) that differ only in the new characters evolved by the descendent(s). A single species could be the closest relative of any number of descendents with the same degree of divergence. An ancestor and its descendent will always have a greater genetic similarity and fewer character changes than paired descendents of the same ancestor.

Cladistics or phylogenetic systematics is a methodology guided by rules outlined in an extensive body of literature accumulated in the last two decades. We encourage herpetologists to learn enough about the methodology to be able to evaluate these basic assumptions: (1) all characters are equally important and potentially species characters, (2) the degree of genetic similarity or divergence is irrelevant, (3) most ancestors are assumed to become extinct at the time of speciation, and (4) the most closely related species are paired descendents sharing their ancestors' derived characters. The new "species" proposed by Collins

(1991) reflect a methodology that cannot separate subspecies from species; the species concepts derived from cladistic methodology have an inherent bias toward narrowly defined taxonomic units (Donoghue 1985, Echelle 1990, Wiley 1981).

In practice, populations designated as "species" using Wiley's ESC and Donoghue's PSC are essentially derivatives of the original typological species concept—i.e., groups of organisms that differ from others in constant characters. In the nineteenth century Linnaeus had the advantage of using the degree of divergence to recognize different species. As O'Brien and Mayr (1991) point out "typological species concepts are fraught with interpretive difficulties such as . . . full species assignment to reproductively compatible (BSC) subspecies, arbitrary selection of diagnostic characters, and numerous species designations that err in the direction of excessive taxonomic splitting." Phillips (1982) notes that "subspecies, despite all misleading attacks, remain basic units in ornithology" and "if we cease recognising subspecies, we must elevate all notable ones, at least, to species rank, thus destroying the biological species and plunging our classification back toward the early 19th century."

We encourage examination of Collins' proposed taxonomic changes on a case by case basis using knowledge of the animals concerned rather than accept such changes wholesale, and to consider the assumptions that they reflect. Regardless of the philosophy embraced by the systematist, a thorough analysis of a taxon with documented evidence should precede any proposed taxonomic change.

Acknowledgements.—We thank Jerry D. Johnson, Michael J. McCoid, R. Wayne Van Devender, and several anonymous reviewers, for stimulating discussions on reptiles, taxonomy, evolution, speciation, and cladistics. Jessie Piper and Jean Morgan processed the manuscript.

Taxonomic Tyranny and the Exoteric

The vast majority of readers of this journal are not broad-based general biologists steeped in the arcane theories and esoteric practices of systematic biology. That certainly includes most professional herpetologists of my acquaintance. There are today three major schools of taxonomic thought (and uncounted splinter factions) promulgating mutually exclusive, irreconcilable principles and methodologies. Adherents of any one school—evolutionary, phenetic, or cladistic—tend to regard the proponents of the others as hopelessly old-fashioned, insane, and/or dishonest, often with excellent reasons. There is simply no hope that any unified consensus, resulting in a stable scientific nomenclature, will evolve in the foreseeable future. We are in for decades of taxonomic turmoil.

There are no "official," binding lists of "correct" or "accepted" names, and most name-change proposals stand or fall on the basis of the popularity of the animals (big, flashy animals and snakes are split; little, inconspicuous creatures are not) or the popularity of the proposal's author. Almost no one ever critically reviews proposed changes. No journal in herpetology publishes reviews of articles printed in its own pages. There is, therefore, little recourse for those who disagree with a taxonomic change, or who know of proof that facts have been misstated in print.

The burgeoning plethora of taxonomic changes—especially splits—in the last decade or so has gone virtually unanswered by those of us with more classical, broad-based biological or evolutionary points of view. Nevertheless, I have personally questioned and sought to verify statements and judgments made, with dismally disappointing results. Most of the split papers I have read contain faulty observations and simple untruths. I determine these by examination of museum specimens, finding character states are frequently not as reported in the splitting literature.

A great deal of real work—specimen examination, more collecting in geographically critical areas, and use of techniques like mt-DNA and electrophoresis—will have to go into determining the real evolutionary status of dichopatric, geographically replacing forms. My word to the exoteric is beware. Just because somebody publishes a new taxonomic arrangement does not mean anyone has to follow it. Consider carefully the source of opinions and pronouncements, and—whenever possible—try to review the facts. Especially, do not blindly accept proposed changes because you imagine there is some "law" that says you have to. There is none. You do not. For a long time to come we will have to live with taxonomic chaos, which means we will have to constantly make judgments.

Editor's Note: An in-depth rebuttal by J. T. Collins to the commentaries by Montanucci, Van Devender et al., and Lazell will be published in the June issue of *HR*.

On Races, Clines, and Common Names in *Opheodrys*

It is not the purpose of this note to enter the long standing debate about the preferred criteria for designating subspecies in systematic herpetology. Rather, a more limited consideration is addressed: how should the interpreters of the herpetological literature present the findings of that literature in their field guides and lists of common names?

Two questions provide the focus for the present discussion. (1) Should reptiles differing only by having distinctive color patterns that are associated with identifiable geographic ranges be recognized as nominal forms in field guides and lists of common names? (2) Should reptiles differing only by having distinctive scutellation patterns that are associated with identifiable geographic ranges be recognized as nominal forms in field guides and lists of common names? Some current authors have responded affirmatively to the first question and negatively to the second. An examination of the reasons proposed by those authors for the difference in their responses is the basis for this note.

In the first edition of *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, Collins et al. (1978) give common names for the two races of *Opheodrys vernalis* that had been described previously (Grobman 1941) and do so in the second edition (Collins et al. 1982). In the third edition, however, Collins (1990) does not provide common names for the two races of *O. vernalis* nor for the four races of *O. aestivus* that had been described in the interim (Grobman 1984). The reason given was that the racial differences found in those two species are based on clinal variations in scutellation characteristics (Collins 1990).

Presumably the precedent established in Collins (1990) was followed in the third edition of *A Field Guide to Reptiles and Amphibians of Eastern and Central North America* (Conant and Collins 1991). Conant and Collins explain that the races of *Opheodrys vernalis* and of *O. aestivus* are not included because the differences in scutellation patterns are not correlated with color pattern differences. Thus, they suggest, it would be difficult for a user of the book to identify the races of *Opheodrys* without counting scales. Elsewhere they recommend that the forms of *Trachemys, Pseudemys,* and *Chrysemys* (p. 64), of *Cryptobranchus* (p. 241), of *Acris* (p. 218), and of the Plethodontidae (p. 259), could best be identified by reference to geography. That recommendation would appear to be equally appropriate for unicolored snakes.

For the recognition of races of snakes, differences in scutellation patterns presumably are as systematically significant as are differences in color patterns. The uneven treatment of the two groups of morphological characters, as indicators of racial differences, misleads readers of the third edition of the *Field Guide*.

The related reasons are faulty, both in fact and philosophy. There are north/south clines, associated with ambient temperature gradients, in scutellation characteristics in the two races of *O. vernalis*, but the scutellation differences between the two races are associated with vegetational differences and are not clinal

(Grobman 1941:27). A considerable number of statistical details are given about *O. aestivus* (Grobman 1984:155-157) demonstrating that there are north/south, not east/west, clines in scutellation and that the metameric variation, upon which the four races are partially based, is not primarily clinal.

The example given by Frost and Hillis (1990) in support of their reasonable position that, ". . . the subspecies category has been long abused for use in naming arbitrarily defined 'slices' of clines (e.g., the arbitrary delimitation of a number of 'subspecies' in *Opheodrys aestivus* by Grobman, 1984) . . ." is therefore inappropriate. In the paper referred to it is clearly indicated (p. 155) that the clinal variation in ventrals and caudals is north/south whereas the races (except for *O. a. carinatus*) are east/west divisions. The data are exhibited in Tables 1 and 2 (pp. 156-157). *O. a. carinatus* is separated from the other races (p. 165) by the degree of keeling and Figure 2 (p. 169) indicates that *O. a. majalis* is a relatively short-tailed race and that *O. a. conanti* is a diminutive subspecies. The described races are not arbitrary slices of clines.

Smith (1990) found that five male hatchlings of *O. aestivus*, incubated at ca. 27.8°C, had a mean ventral count of 155.6 and three male hatchlings, from the same clutch of eggs, incubated at ca. 24.8°C had a mean ventral count of 159.0. That observation led him to suggest that ". . . if many ophidian species respond to temperature during development, these counts may not be satisfactory criteria of gene flow. . ." The demonstrated effect of the north/south temperature gradient (Grobman 1984:155) would appear to be sufficient to account for Smith's observation. His study does not provide an adequate basis for his extended suggestion that ventral counts are not indicative of racial differences. Furthermore, as indicated above, the races of *O. aestivus* are distinguishable on other characteristics as well.

The readers of the third edition of the *Field Guide* would be better served had the races of *Opheodrys* been identified and the users of common names would be better served had the third edition of Collins (1990) supplied such names for those races. The underlying reason for those omissions apparently was the assumption that the scutellation clines in *Opheodrys* were used to define the described races. A more careful reading of the descriptive accounts would have made it clear that the north/south clines in *Opheodrys* are not the basis for recognition of the essentially east/west races.

A demonstration that color patterns (used in classification schemes) are primarily under genetic control and that scutellation patterns are not, would provide a reasonable basis for questioning the use of the latter as indicators of taxonomic distinctions. I know of no such demonstrations, however.

Acknowledgment.—Hobart Smith has read an early draft of the manuscript and I am grateful to him for the suggestions he has made.

Reply to Grobman on Variation in *Opheodrys aestivus*

Grobman (this issue of *Herpetological Review*) disagrees with the taxonomic arrangements for the green snakes, *Opheodrys aestivus* and *O. vernalis*, in Collins (1990) and Conant and Collins (1991). He points out that, in the first two editions of *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, Collins et al. (1978, 1982) initially recognized the races of *Opheodrys vernalis*, but did not do so in the third edition (Collins 1991), and questions why neither these races nor those proposed by him (Grobman 1984) for *Opheodrys aestivus* were recognized.

With respect to Collins (1990), the decision to not recognize races of the snake genera *Opheodrys* (and *Tropidoclonion*) was made by vote of a committee of snake systematists (see p. 2), an action initiated by the publication of Grobman's (1984) taxonomic proposals for *O. aestivus*. Conant and Collins (1990) had independently decided to not recognize races for *Opheodrys* because the diagnoses for the subspecies were suspect. Nothing in Grobman's paper (this issue) dispels that concern.

Grobman (1984) proposed four new races of *Opheodrys aestivus*, presenting his data in tabular form (Tables 1–10). None of the scutellation data contained in those tables was tested for statistical significance, nor were they subjected to univariate or multivariate analysis, and all are suspect. Further, the main characteristics defining his races reside in his key (p. 167), in which he created a situation whereby intergrades between his proposed four populations would, minimally, have to exhibit 127.5 ventral scales—in other words, his statements in this issue to the contrary, he has arbitrarily sliced clines, whether they be east-west or north-south. Grobman (this issue) attempts to discredit Smith (1990), who incubated the eggs of *O. aestivus* and varied the ventral counts by varying the temperature, when in fact this phenomenon was earlier revealed by Fox et al. (1961), when they sounded the death knell for defining subspecies based on ventral and subcaudal scale count variation over 30 years ago.

Grobman (this issue) further questions the continued recognition of subspecies based on pattern and color in both Collins (1990) and Conant and Collins (1991). With respect to Collins (1990), a committee of snake systematists evaluated all taxonomic changes proposed *between* editions. These proposals, published from 1982 to 1989, were submitted to the snake subcommittee, and they voted not to recognize the races of *Opheodrys* and *Tropidoclonion*. The decision was not an arbitrary one—Grobman just doesn't like the result. If, in the same time frame, articles had been published proposing the elimination of races based on color and/or pattern, the snake subcommittee would

have evaluated and voted on those also. With respect to Conant and Collins (1991), the decision not to recognize subspecies of *Opheodrys* and *Tropidoclonion* was reached early (in the mid-1980s), was a personal decision, and was unrelated to the list published by Collins (1990).

In conclusion, it is my opinion that Grobman (1984) presented no evidence that justifies the recognition of subspecies in *Opheodrys aestivus* and, for that reason, I recommend that the herpetological community not recognize his subspecies and hold future such proposals to standards of analysis designed to divulge evolutionary (historical) reality.

The Adoption of the Poison-arrow Frogs of the Genera *Dendrobates* and *Phyllobates* in Appendix II of CITES

Conservation of amphibians and reptiles involves scientific herpetology in many ways. One of these is that species protection must be based on scientific investigations. The inclusion of *Dendrobates* spp. and *Phyllobates* spp. in Appendix II of CITES (Convention on International Trade in Endangered Species) is being discussed widely among herpetologists. In Hoogmoed's (1990) book review the protection of dendrobatids is emphasized in a singular way. Since there is obviously a general interest in protection, I will in the following give comments on that subject.

The inclusion of *Dendrobates* spp. and *Phyllobates* spp. in Appendix II of CITES was decided upon at the biennial meeting in Ottawa during July 1987. Its basis has been strongly criticized (cf. Mrosovsky 1988; Pickett 1987). After Hoogmoed's (1990) review I feel there is more than ever a need to cast light on this inappropriate action. The Appendix II listing means a regulation of the trade; however, for these common and abundant frogs it will merely mean a regulation for the sake of regulation. The proponents (Surinam and The Netherlands) were unable to provide any indication of decreasing populations; in the supporting material it was merely stated: "Population data are scarce." Scattered statistics on the international trade in various species were given.

Prior to the Ottawa meeting the proposals were analyzed in two reports by the IUCN Trade Specialist Group. These were largely based on the work of Charles Myers (American Museum of Natural History), one of the few herpetologists who has studied dendrobatids extensively in the wild. The other reviewers were Stephen Edwards, Stefan Gorzula, and Marinus S. Hoogmoed. The reports contain many interesting comments; I shall quote or summarize a few of these factual details.

1. The species are easy to identify (only Hoogmoed comments on the small genus *Phyllobates* comprising 5 species: ". . . some species are likely to be confused with others").
2. Those dendrobatids that most often appear in international trade have generally large ranges and are among the most abundant vertebrates in their habitats—e.g., species densities of up to 10 adults per m^2.
3. There is no knowledge of range contractions in historic times.
4. No species are threatened.
5. *D. histrionicus* occurs in countless dense populations throughout many thousands of km^2 of undisturbed rain forest in western Colombia and Ecuador; however, in Surinam's proposal *histrionicus* is just described as "relatively common."
6. The few heavily collected populations of *D. auratus* and *D. pumilio* remain as dense as ever.
7. There is no evidence that dendrobatids are dependent on primary forests. Certainly they are to be found in undisturbed forest, but the highest densities are frequently in disturbed areas, such as mixed secondary growth.
8. Myers reports that during a four-year study on *D. histrionicus*, during which he collected 7600 specimens from one population for scientific purposes, the population actually increased rather than decreased. This number greatly exceeds the imports of all dendrobatids into the U.S. in 1985 and The Netherlands in 1984-1985. Similar cases are known. In no single instance has collecting appeared to adversely influence the population.

TRAFFIC Network (funded by WWF and coordinated by IUCN) gave a clear recommendation to each of the two proposals before the CITES meeting in Ottawa: "This proposal should be rejected as it does not provide any evidence of a threat arising from trade."

The decision at the Ottawa meeting was evaluated by Mrosovsky (1988): "The proposal . . . was passed largely with the support of the South American countries who may have voted more in a spirit of regional solidarity than on the basis of scientific evidence." Also, the EEC countries as a whole supported the proposals. Again, indiscriminate block voting undermines the credibility of CITES in such cases. Mrosovsky (op. cit.) fears that this "could turn CITES into a circus for political exhibitionism."

As soon as *Dendrobates* spp. and *Phyllobates* spp. had been included in Appendix II of CITES, they were also adopted in Annex C part 2 of the EEC Regulation (accomplishing the Convention within the European Community). WWF-Denmark protested in a letter by Arne Schiøtz (former Director of Conservation of WWF-International) to the Danish National Forest and Nature Agency; Peter Kramer (Director of Conservation, WWF-International) and all WWF National Organizations within EEC received copies. Schiøtz stated:

> "One of WWF's consistent arguments for conserving natural habitats is that they can, if exploited sustainably, benefit local people and the countries in which they occur. The argument is of course difficult to maintain if, equally consistently, groups with other interests prevent such sustainable utilization."
> "There are many well-founded reservations about keeping wild

animals in captivity or against the exploitation of wild animals at all, based on animal welfare, but we must be aware that they are contrary to one of the strongest arguments for conservation of the natural habitats."

Hoogmoed (1990) states that all species of *Dendrobates* and *Phyllobates* were listed for look-a-like reasons as this would facilitate the protection of an endangered species which may be confused with other species. Firstly, according to the IUCN reports there are no real look-alike problems. Secondly, no dendrobatid species has been demonstrated or suggested to be endangered. Thirdly, if one should manage to find an endangered dendrobatid species which may be confused with another species, it would be fully sufficient merely to protect these two species. This has been done with the Asian look-alike species *Rana tigerina* and *R. hexadactyla*, which were included in Appendix II in 1985—although it is especially *R. tigerina* that has been over-exploited for the export of frog legs. It would have been senseless to adopt the entire genus *Rana* in Appendix II just because *R. tigerina* needs protection and may be confused with another species!

In addition to the issue of conservation, Hoogmoed (1990) also expresses an undertone of disapprobation of terrarium-keeping. By maintaining non-threatened species (e.g., poison-arrow frogs) properly in a rain forest terrarium and reading literature on how to fulfill their captive requirements, the terrarium-keeper may gain valuable insight in rain forest ecology. What may be even more important is the personal engagement in the ecological world crisis and the awareness and understanding of the natural world. In professional journals the amateurs seldom meet a forum to defend their activities or to take positions against unfounded imputations of being the culprits of destruction. Böhme (1990) has stressed the important role of amateur terrarium-keeping to herpetology (although in a discussion of national German legislation). That issue deserves a separate forum.

For the larger public, unjustified CITES protection impugns the reputation of the Convention. In the case of *Dendrobates* spp. and *Phyllobates* spp., the only way to improve the reputation and to clear this embarrassing issue will be to remove these frogs from CITES as soon as possible.

TECHNIQUES

Methods of Sampling Snake Populations and Their Relative Success

Snakes are difficult subjects for field study because of their secretive habits. During 43 seasons of continuous field work on the University of Kansas' Fitch Natural History Reservation (FNHR), northeastern Kansas, several sampling methods used have had variable degrees of success. Here I compare the numbers of captures, by species, using (1) live-traps (LT), (2) artificial shelters (AS), and (3) random encounters (RE) during the decade of the 1980s, through May 1991.

Three areas sampled included the 240-ha FNHR, the University's 175-ha Nelson Environmental Area adjoining the Reservation's north side, and Chester Fitch's property of 4.2 ha, 0.8 km west of the Reservation. Various types of woodland occurred on the FNHR, with former pastures and cultivated fields undergoing invasion by trees and shrubs. The Nelson Environmental Area, and the Chester Fitch property at the edge of the Kaw River Valley mainly consist of naturally vegetated fields kept in an early stage of succession by periodic mowing. My snake sampling operations were scattered over an area of several hundred hectares, but were relatively concentrated within 28 sampling units in all, each limited to only a few hectares. Only a few of these units were sampled in any one year, with occasional testing of new units and abandonment of the less productive units.

The live-traps used have been described elsewhere (Fitch 1951, 1987). Most were of quarter-inch (6 mm) wire "hardware cloth" shaped into cylinders ca. 370 mm long and 125 mm diam, with funnel openings 25 mm diam, but some were larger and some were of finer mesh wire. On the FNHR each spring and early summer through 1989, about 100 of these traps were used in pairs—one at each end of a drift fence 4–7 m long. In the fall, the same traps were used at hilltop limestone outcrops where many snakes came to hibernate, and the exposed vertical rock faces provided natural barriers that served as drift fences. Fourteen such outcrops with total linear extent of 3.25 km were sampled. In 1990-91 trapping operations were transferred to the Nelson Experimental Area where there were six enclosures of several hectares each, fenced with fine wire mesh to confine or exclude small mammals. Traps were placed in linear patterns along the hilltop outcrops and enclosure fences, but in three upland fields and one lowland field they were used in random patterns.

Artificial shelters (AS), 300 in all, consisted of corrugated roofing metal or wood; many were 0.6 X 1.2 m, while others were of irregular sizes. They were placed in seven series with 25–100 AS in each. Two arrays were at the edge of the Kaw River Valley and five were in adjacent uplands. Three of the latter were arranged linearly and were checked at irregular intervals. Three series (installed in 1989) that were relatively unproductive were seldom checked. By far the most productive were 40 in "Quarry Field," an upland 3.7-ha area on the northern edge of the FNHR. A series of 100 AS in the southeastern corner of the Nelson Environmental Area and 30 on the Chester Fitch property also yielded substantial numbers of records and a variety of species. Shelters had the advantage of avoiding injury or mortality to snakes, whereas live-traps caused occasional injuries and some mortality when temperatures were extreme, when predators such as raccoons tore open the traps, when trapped snakes became stuck between the wires, or when confined snakes were attacked by shrews and rodents caught with them. Another important advantage of AS was that snakes using them often

were digesting meals and a relatively high percentage of them had stomach items that could be palped and identified. Thus 23 of 90 *Agkistrodon contortrix* (25.6%) had food in their stomachs whereas only 34 of 559 from LT (6.1%) had such items.

The random encounter (RE) category included all captures that were not from LT or AS. Some snakes were found in open places including roads and driveways (DORs were not counted), some were beneath natural shelters, and some in thick cover were revealed by the scolding of birds, but overall, RE constituted only 3.2% of the total captures.

Numbers and proportions of snakes captured by the three different methods are given in Table 1. The most productive method, accounting for slightly more than 67% of the total records, was AS, while the LT method comprised 29% of the captures. Four species were obtained only from shelters, and for two others shelters provided the majority of records. Snakes obtained mainly or exclusively from shelters included the small, secretive species *Carphophis amoenus, Diadophis punctatus, Storeria dekayi, Tantilla gracilis*, and *Tropidoclonion lineatum*. These snakes are too small to be retained in traps with quarter-inch wire mesh. The two largest snakes on the area, *Pituophis catenifer* and *Crotalus horridus*, were the only species for which RE was the most productive method.

Live trapping was most successful with snakes of intermediate size (0.4–1 m SVL): *Agkistrodon contortrix, Coluber constrictor, Elaphe obsoleta, Lampropeltis calligaster, L. getula*, and *Thamnophis sirtalis*. For each of these, LT yielded more records than AS and RE combined. Snakes much longer than 1 m SVL may have been too large to pass through a funnel's entrance, and those that were much less than 0.4 m SVL could pass through the mesh of the traps unimpeded. Such relatively large or small snakes could have been caught by adjusting the size of the trap body, the type of material used, and the diameter of the funnel opening. For instance, in the 1960s, with effort concentrated on catching small snakes such as *Carphophis* and *Diadophis*, traps were made using one-quart (0.95 l) glass "Mason" jars as bodies and eighth-inch (3 mm) wire for funnels, with entrances 1 cm diam (cf. Clark 1966). In the 1966 season, when about 50 such traps were used, a total of 1639 *Diadophis* captures were recorded; 698 (42.6%) were in the small funnel traps, and, simultaneously these traps also caught numbers of *Carphophis amoenus, Storeria dekayi*, and first-year young of *Thamnophis sirtalis, Nerodia sipedon*, and *Coluber constrictor*.

For the 16 species of snakes captured during the 1980-1991 sampling, the three methods (LT, AS, and RE) combined yielded the following capture percentages:

Diadophis punctatus	59.1%
Coluber constrictor	12.2%
Thamnophis sirtalis	10.5%
Agkistrodon contortrix	9.6%
Elaphe obsoleta	3.1%
Elaphe guttata	1.4%
Lampropeltis triangulum	1.4%
Lampropeltis calligaster	1.1%
Nerodia sipedon	0.6%

The seven rarest species, *Pituophis catenifer, Carphophis amoenus, Crotalus horridus, Storeria dekayi, Lampropeltis getula, Tantilla gracilis*, and *Tropidoclonion lineatum* combined were less than one percent of the total captures.

The incidence of recaptures from the three sampling methods combined differed among the various species, as follows:

Lampropeltis triangulum	85.0%
Elaphe guttata	58.0%
Coluber constrictor	42.5%
Lampropeltis calligaster	36.9%
Agkistrodon contortrix	29.6%
Thamnophis sirtalis	27.0%
Pituophis catenifer	25.0%
Elaphe obsoleta	23.0%
Nerodia sipedon	13.3%

There were no recaptures of *Carphophis amoenus, Crotalus horridus, Lampropeltis getula, Storeria dekayi, Tantilla gracilis*, or *Tropidoclonion lineatum*. The high ratio of recaptures in *Lampropeltis triangulum* and *Elaphe guttata* stems from their relatively low vagility and tendency to return to the same cover; few individuals of each were captured but most of these were taken on several or many occasions. No *Diadophis* were individually marked during the decade of the 1980s, so the ratio of recaptures in the 4179 records of Table 1 is unknown. However, in 1969, the year after marking was discontinued, 503 captures included 79 (15.7%) of marked snakes.

TABLE 1. Snakes captured by three methods, 1980-1991, on three areas in Douglas, Jefferson, and Leavenworth Counties, northeastern Kansas.

Species	Total Number of Captures	Percentage Captured by Method: Live-Traps (LT)	Artificial Shelters (AS)	Random Encounters (RE)
Agkistrodon contortrix	678	83.0	13.3	3.7
Carphophis amoenus	16	0.0	100.0	0.0
Coluber constrictor	862	87.5	12.1	0.4
Crotalus horridus	13	38.5	15.4	46.2
Diadophis punctatus	4,179	0.0	98.4	1.6
Elaphe guttata	100	0.0	100.0	0.0
Elaphe obsoleta	218	54.6	24.3	21.1
Lampropeltis calligaster	76	55.4	26.4	18.2
Lampropeltis getula	2	100.0	0.0	0.0
Lampropeltis triangulum	99	18.2	78.8	3.0
Nerodia sipedon	45	35.5	57.8	6.9
Pituophis catenifer	20	25.0	25.0	50.0
Storeria dekayi	7	0.0	100.0	0.0
Tantilla gracilis	1	0.0	100.0	0.0
Thamnophis sirtalis	744	71.5	23.0	5.5
Tropidoclonion lineatum	2	0.0	100.0	0.0
Totals	7,062	29.0	67.7	3.3

In summary, a twelve-year record of 16 snake species on an area of several hundred hectares demonstrated that each species differed in abundance, distribution, and probability of capture by three different methods. The data demonstrate that each method of sampled used was successful to varying degrees, depending on the species, and was totally ineffective for some species. The most effective method of sampling for eight species was AS, followed by LT for six species, and RE for two species (Table 1). One advantage of AS over LT was that shelters greatly reduced the risks of mortality or injury, and they yielded a high percentage of snakes with food in their stomachs that could be identified. Installation of AS involved relatively little time and effort (and expense) compared with installation of LT with drift fences. Also, AS are less restrictive for the investigator as they can be checked when convenient or left untended, whereas LT need to be tended regularly and involve a major commitment of time. Effective use of AS requires, however, that they be checked at the time of day when snakes are most likely to take shelter beneath them. I found it was futile to check shelters when they were too hot or too cold to be attractive. In most community studies of snakes, a combination of field sampling methods may be desirable in order to ameliorate the biases that arise from sexual, seasonal, and ontogenetic differences in behavior among the local assemblage of species.

Blood Collection From *Macroclemys temmincki* (Troost)

Several methods are available for the collection of blood samples from turtles, including heart puncture through the plastron (Dessauer 1970; Maxwell 1979), toenail clipping (Frye 1991), and cutting off the end of the tail or sacrificing the animal (Duguy 1970). Blood samples also can be obtained from the femoral vein, jugular vein, or the carotid artery (Maxwell 1979). Microliter amounts of blood can be obtained from orbital vessels (Maxwell 1979), and blood can be collected from the dorsal cervical sinus of hatchlings (Bennett 1986). Blood sampling from alligator snapping turtles (*Macroclemys temmincki*) by heart puncture, however, presents several difficulties, especially in larger individuals with thick plastrons. The size and aggressiveness of these turtles make the use of limbs or neck vessels difficult. Sacrificing the animal is not desirable as they are rare, and toenail or tail clipping often does not provide a blood sample sufficient for multiple analyses. Following the methods suggested by Galbraith (pers. comm.), we have adapted his procedure for obtaining blood samples from the ventral caudal vein of *Chelydra serpentina* for use in *Macroclemys temmincki*.

To obtain a blood sample, the turtle was placed on its carapace. We found one or two metal crates (47 cm x 32 cm x 27 cm) to provide an adequate work surface upon which to balance the turtle. When handling turtles over 20 kg it was safer to use two persons to position the animal. The limbs were left unrestrained and the head allowed to hang free. The elevation of the work area was such that the turtle could not use its head for leverage. In this position, the turtle remained docile. Precautions were taken to avoid the immediate area of the head and claws of the hind limb, and movement in the vicinity of the head agitated the animal and provoked snapping.

After positioning the turtle, the ventral surface of the tail posterior to the cloaca was washed with Betadine (Povidone-iodine 10%, Purdue Frederick Co., Norwalk, Connecticut) solution. The tail was then grasped firmly with one hand, and a 1 inch, 22-gauge, Luer-Lok hypodermic needle attached to a 5-cc syringe (rinsed with sodium heparin) was used to obtain the blood sample. The ventral midline of the tail was palpated until the protrusions of the adjacent chevron bones which descend from the caudal vertebrae and form the haemal arches were felt (Galbraith 1991). The needle was inserted at a right angle into the space between the fourth and fifth chevron bones, and the caudal vein punctured. Gentle vacuum was applied until blood appeared in the syringe, then stronger vacuum applied until a sufficient sample of blood was drawn (usually 1-3 ml). The needle was withdrawn and pressure applied to the area until bleeding stopped. Excess blood was washed off the tail, and the area was swabbed with Betadine. Use of a syringe rather than Vacutainer blood collection tube was found to give better control of the process.

After collection, the blood was transferred to sterile tubes (Monoject Blood Collection Tubes/143 USP units sodium heparin) for storage until analyzed. Heparin was used as the anticoagulant instead of EDTA because hemolysis of the red blood cells is known to occur with EDTA (Dessauer 1970). Although not available for this study, it should be noted that lithium heparin is now the anticoagulant of choice for chelonian blood studies (Frye 1991).

Using this technique, blood samples have successfully been collected from 25 alligator snapping turtles ranging in size from 14 to 56 cm carapace length and weighing 2 to 45 kg (Powell and Knesel 1991). Repetitive blood sampling from these turtles over a six-month period has not produced visible harm to the animals.

Acknowledgments.—We are grateful to David A. Galbraith for sharing his blood collection techniques with us at the SSAR annual meeting in New Orleans.

An Alphanumeric Code for Toe Clipping Amphibians and Reptiles

Toe clipping is one of the most widely used techniques for individual marking of anurans and lizards. The system proposed by Martof (1953), and other systems cited by Ferner (1979), require the amputation of four or more toes to obtain several two or three-digit numbers. Hero (1989) proposed a system that

requires less amputation and allows the individual marking of 736 anurans by removing up to three toes. However, this system does not use all available combinations of toes because it assigns numerical series to the digits. Also, one must remember which combinations are not available.

I propose a system that assigns letters to the feet and numbers to the toes (Fig. 1). Therefore, all the combinations available for two and three toes can be obtained, with the single condition of not amputating more than two toes for each limb (Table 1). Using this code, clipping up to three toes allows marking of a maximum of 959 individual anurans (4 toes/forelimb, 5 toes/hindlimb), and 1310 lizards (5 toes/forelimb, 5 toes/hindlimb). The researcher can discard combinations that require the amputation of more than one toe on the same limb, or avoid other inappropriate combinations, such as those that involve clipping thumbs in species that use these for amplexus or fighting.

A number can be assigned to each code without the necessity of discarding codes. This also minimizes the mistakes due to two numbers having the same code in Hero's system (e.g., 708 and 807). However, with the ready availability of microcomputer spreadsheets that can sort and find codes on any alphanumeric system, most researchers will probably simply scratch each toe code off the list as it is used rather than risk the added complication of parallel numeric and alphanumeric systems. The code system can be photocopied and used by any researcher with the assurance that, within any self-imposed restrictions, the maximum number of two and three toe combinations are being utilized.

Acknowledgments.—I would like to thank William E. Magnusson and Thierry R. J. Gasnier for the suggestions given during the preparation of this note.

RECENT POPULATION CHANGES

Return of *Cyclura carinata* to Pine Cay, Turks and Caicos Islands, BWI

One of the most interesting examples of local extirpation by introduced human pets gone feral is that of the rock iguana

The classic series, now in paper

BIOLOGY OF THE REPTILIA

Edited by Carl Gans

The University of Chicago Press is honored to become the publisher of this series, beginning with Volume 17. Under the editorship of Carl Gans, who has directed the series since its inception, series volumes will continue to provide the most comprehensive reviews in print of reptilian morphology, physiology, behavior, and ecology.

Sensorimotor Integration

Edited by Carl Gans and Philip S. Ulinski

This volume focuses chiefly on visual and sensorimotor aspects of reptilian neurobiology, emphasizing results from recent studies. Chapters examine data for numerous species, drawing together the most current work and thinking on each topic.

Volume 17, Neurology C

Paper $42.50 784 pages
115 halftones, 177 line drawings, 17 tables

Hormones, Brain, and Behavior

Edited by Carl Gans and David Crews

This is the first volume to synthesize information on ways in which the nervous and endocrine systems interact to mediate crucial aspects of reptile behavior. The authors pay particular attention to reproductive behavior, and also deal with other survival behaviors.

Volume 18, Physiology E

Paper $34.00 (est.) 536 pages (est.)
30 halftones, 65 line drawings, 27 tables

Cyclura carinata from Pine Cay, Turks and Caicos Islands, British West Indies (Iverson 1978, 1979). Iverson (1979) recorded the systematic decline from 1973 to 1976 of a very large population to a relatively small one, that ended in total extirpation by 1978 (Iverson 1978). This extirpation was believed to have been caused by feral cats and dogs introduced during modern human settlement of the island. Nearby undeveloped islands lacking feral mammals (Ft. George and Little Water Cays) apparently have maintained relatively large iguana populations.

During a visit to Pine Cay from 13 to 28 July 1991, I searched for evidence of a return of *Cyclura carinata* to the island. Of 107 h spent walking the entire island, 22 h were spent on two study sites (see Fig. 1). Iguana tracks were found at several locations on the island. At one location opposite Ft. George Cay, many tracks were found, whereas at other locations only a single set of tracks was found. No iguanas were directly observed. However, residents of Pine Cay informed me that there are at least two individuals on the island, one of which is a large male. Indeed, sightings by residents occurred during my stay on Pine Cay. Residents also reported that these sightings began only within the previous year, and that no iguanas had been seen in the preceding ten years.

Two observations lead me to believe that the tracks and sightings were of *Cyclura carinata*. First, the tracks consisted of a single, continuous tail track bracketed by claw marks similar to other iguana tracks previously observed by the author (photographic slides were taken of several sets of tracks), and second, I believe that the sightings by the residents are reliable. All residents reporting iguanas were present when the iguanas previously inhabited the island, and all have also seen iguanas on the nearby Ft. George and Little Water Cays. Finally, *Cyclura carinata* is the only large lizard found in the Turks and Caicos Islands (Schwartz and Henderson 1988).

Therefore, it appears as though the rock iguana has returned to Pine Cay, although the source(s) of the recolonizing individuals is unknown. Three possible sources of iguanas exist: 1) Ft. George Cay, which is consistent with numerous tracks on the northeast end of the island; 2) Little Water Cay, a doubtful source because it would necessitate dispersal across Water Cay (an island approximately the same size as Pine Cay); and 3) reintroduction by humans.

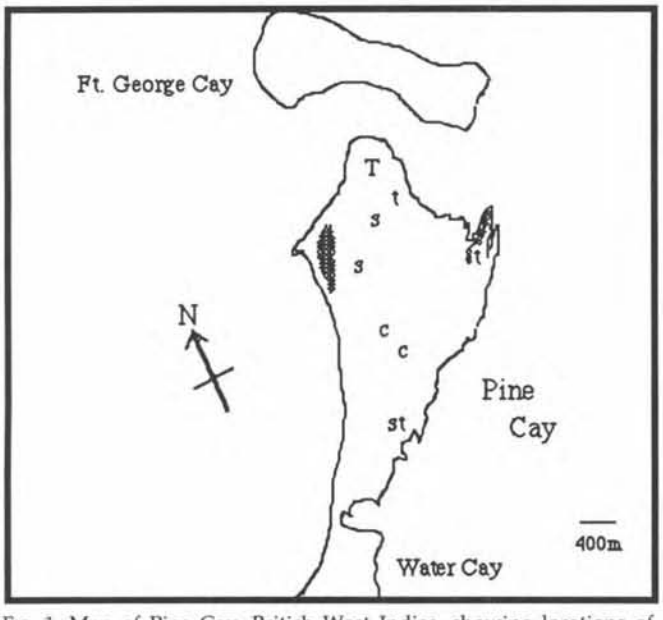

FIG. 1. Map of Pine Cay, British West Indies, showing locations of reported sightings (s) and tracks (T or t) of *Cyclura carinata*. The capital 'T' indicates area where several tracks were found on many occasions. Sightings of feral cats or presence of cat tracks are shown by the 'C's. Shaded areas indicate locations of the main study sites. Little Water Cay is found to the southwest of Water Cay. For a more detailed map see Iverson (1979).

HERPETOLOGISTS

The Environmental Sciences Department of EG&G Energy Measurements in Las Vegas, Nevada, is expanding its staff of research ecologists. The department assesses, monitors, and mitigates impacts of Department of Energy-sponsored activities on biological resources at the Nevada Test Site. Studies encompass ecological communities and federal/state-protected plants and animals. Herpetologists with B.S. (with additional experience), M.S. or Ph.D. will be considered for the positions. Herpetologists will participate in:

- interdicsiplinary community ecology studies
- threatened/endangered species studies and conservation
- impact assessment and mitigation

Projects at the Nevada Test Site evaluate and mitigate impacts of diverse activities on the threatened desert tortoise and protected plant species. Broader impact assessment and mitigation studies on general plant, invertebrate, and vertebrate populations and communities also are being conducted.

Job responsibilities will vary and include assessing impacts of activities on biological resources; developing new studies on impact assessment/mitigation or reclamation in area of specialization; implementing field studies (including supervising field crews); and analyzing data, preparing reports, and presenting information to sponsors.

Positions available immediately. Qualified candidates should send a resume, transcripts, an example of writing, and a completed application form to the address below. Additional information can be obtained from:

EG&G Energy Measurements, Inc.
Human Resources Division
Attn: Pat Ullom, 09-92
P. O. Box 1912
Las Vegas, Nevada 89125
(702) 295-0319

An Equal Opportunity Employer. Female and minority applicants are encouraged to apply. U.S. citizenship and pre-employment physical, which includes drug screening, required.

Prospects for survival of the returning iguanas are tenuous. The size of the current population is probably very small (< 10). Human development on Pine Cay continues and may present some future danger to the continued presence of the iguanas. At present, however, iguana habitat is being preserved and human disturbance appears minimal. Finally, the initial cause of the extirpation from the island (i.e., feral cats) is still present. Cat tracks were seen on all parts of the island, and cats were observed twice during my fieldwork (see Fig. 1). These cats may reduce the likelihood of successful repopulation of Pine Cay by iguanas.

Acknowledgments.—I thank J. Garis, manager of the Meridian Club, and the residents of Pine Cay (especially W. and Z. Brewer and G. Nipanich) and P. Neis for their assistance and hospitality during my stay on Pine Cay. Support was provided by an NSF predoctoral fellowship, an ASIH Gaige Fund award, the H. Holck fund of the University of Nebraska School of Biological Sciences, and T. and J. Smith. J. Iverson, R.

Ballinger, and J. Rowe provided useful comments on early drafts of this manuscript.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19:1–41), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author — curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985(3):802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full — spell out state names — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. All specimen identifications *must* be verified by another authority (not one of the authors). Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to the Section Co-editors, Joseph T. Collins (USA & Canadian records only), Museum of Natural History — Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454, USA, or Darrel Frost (the rest of the world), American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024, USA. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Phillips, C. A. 1991. Geographic Distribution. *Ambystoma maculatum*. Herpetol. Rev. 22:133.

CAUDATA

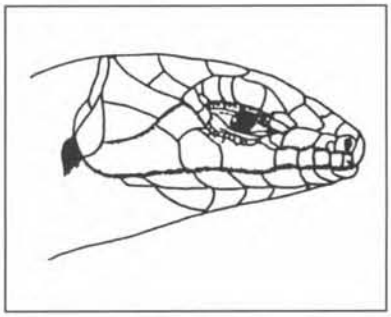
AMBYSTOMA MACULATUM (Spotted Salamander). USA: TENNESSEE: Rutherford Co: Fall Creek Road, 1.5 km N jct. Mona Road (36°00'42"N, 86°26'18"W). 5 February 1991. B. T. Miller (Tennessee Scientific Study Permit 418). Verified by D. E. Metter. Middle Tennessee State University (MTSU 46C). County record (Redmond 1985, A biogeographic study of amphibians in Tennessee, Doctoral Dissertation, Univ. Tennessee, Knoxville, 290 pp.).

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

CRYPTOBRANCHUS ALLEGANIENSIS ALLEGANIENSIS (Eastern Hellbender). USA: TENNESSEE: Marion Co: Little Sequatchie River at new Rt. 28 crossing. 7 June 1991. J. L. Miller & B. T. Miller. Middle Tennessee State University (MTSU Photograph 48-C). New county record that verifies suspected distribution in the Cumberland Plateau physiographic region of middle Tennessee (Redmond 1985, A biogeographic study of amphibians in Tennessee, Doctoral Dissertation, Univ. Tennessee, Knoxville, 290 pp.); Warren Co: Collins River at Rt. 127 crossing. 6 June 1991. J. L. Miller & B. T. Miller. MTSU 47-C. Found dead along shoreline two days after heavy rains and flash floods. New county record that verifies suspected distribution in the eastern Highland Rim physiographic region of middle Tennessee (Redmond op. cit.). Both collected under Tennessee Scientific Study Permit 418 and both verified by D. E. Metter.

Submitted by **BRIAN T. MILLER** and **JOYCE L. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

PSEUDOTRITON RUBER (Red Salamander). USA: TENNESSEE: Coffee Co: small spring-fed creek off Lyndell Bell Road, 2.9 km S Blantons Chaple Road. 20 March 1991. B. T. Miller (Tennessee Scientific Study Permit 418). Verified by D. E. Metter. Middle Tennessee State University (MTSU 43C). County record (Redmond 1985, A biogeographic study of amphibians in Tennessee, Doctoral Dissertation, Univ. Tennessee, Knoxville, 290 pp.).



Submitted by **BRIAN T. MILLER** and **JOYCE L. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

ANURA

BUFO BRONGERSMAI (Brongersma's Toad). MOROCCO: Prefecture of Marrakech: Skhour-des-Rehamna, 137 km S Casablanca on road to Marrakech (32°30'N, 07°55'W). 29 March 1991. Ignacio de la Riva. Verified by M. Garcia Paris. Museo Nacional de Ciencias Naturales, Madrid, Spain (MNCN 16616). Second extra-Saharan record, 120 km NE from the first one by Distre et al. (1989 Bull. Soc. Herp. Fr. 51:19–26).

Submitted by **IGNACIO DE LA RIVA**, Departamento de Biologia, Facultad de Veterinaria, Universidad de Las Palmas, C/Francisco Inglott Artiles 12A, 35016 Las Palmas de Gran Canaria Islands, Spain.

Guide to the Reptiles and Amphibians of the Savannah River Site

J. Whitfield Gibbons and Raymond D. Semlitsch

Most of the reptiles and amphibians found in Georgia and South Carolina are represented at the Savannah River Site, a 780-square-kilometer tract that is one of the most intensely studied areas of its kind in the world.

This guide is a summary of basic information on the site's more than one hundred species of reptiles and amphibians, from their taxonomy and distribution to their behavior and habitats, as well as the techniques and special problems of collecting and identifying specimens. Enhancing the text are four maps and 26 line drawings.

BUFO COGNATUS (Great Plains Toad). USA: NEBRASKA: Cherry Co: ca. 30 km N Mullen, Nebraska on State Hwy. 97, Sec. 15, T27N, R32W. 27 July 1991. A. T. Holycross. Verified by John Lynch. University of Nebraska State Museum (UNSM 15062). New county record, fills significant gap in known distribution in Nebraska. (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **ANDREW T. HOLYCROSS**, Department of Biology, University of Nebraska at Omaha, Omaha, Nebraska 68182–0040, USA.

BUFO COGNATUS (Great Plains Toad). USA: NEBRASKA: Otoe Co: Camp Creek Cemetery, Sec. 13, T7N, R14E. 26 May 1991. John Lokke. University of Nebraska State Museum (UNSM 15053); Nemaha Co: ca. 4 km S of Little Nemaha River on Nebr. Rt. 67, Sec. 25, T4N, R15E. 1 June 1991. K. B. Malmos and A. T. Holycross. UNSM 15061; Washington Co: ca. 2 km NW Nathan's Lake, Sec. 17, T17N, R13E. 26 April 1991. K. B. Malmos. UNSM 15054. All verified by John Lynch. New county records, fill significant gap in known distribution in Nebraska (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **ANDREW T. HOLYCROSS** and **KEITH B. MALMOS**, Department of Biology, University of Nebraska at Omaha, Omaha, Nebraska 68182–0040, USA.

GASTROPHRYNE CAROLINENSIS (Eastern Narrowmouth Toad). USA: TENNESSEE: Rutherford Co: cedar glade along northern border of Fall Creek Road (36°00'42"N, 86°26'18"W). 4 May 1991. B. T. Miller (Tennessee Scientific Study Permit 418). Verified by D. E. Metter. Middle Tennessee State University (MTSU 36A, 37A). County record (Redmond 1985, A biogeographic study of amphibians in Tennessee, Doctoral Dissertation, Univ. Tennessee, Knoxville, 290 pp.).

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

HYLA GRATIOSA (Barking Treefrog). USA: TENNESSEE: Warren Co: Pigeon Hill Road, 1 km N Rt. 70-S near Centertown. 27 May 1991. J. L. Miller and B. T. Miller (Tennessee Scientific Study Permit 418). Verified by D. E. Metter. Middle Tennessee State University (MTSU 42A). New county record that extends the known distribution into the eastern Highland Rim physiographic region of middle Tennessee (Redmond 1985, A biogeographic study of amphibians in Tennessee, Doctoral Dissertation, Univ. Tennessee, Knoxville, 290 pp.).

Submitted by **BRIAN T. MILLER** and **JOYCE L. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

PSEUDACRIS REGILLA (Pacific Chorus Frog). USA: ALASKA: Alexander Archipelago, Revillagigedo Island: 11 km NW of Ketchikan adjacent to Ward Creek Recreation Area (55°40'N, 131°75'W). 22 June 1991. R. Hauver (U. S. Forest Service). Verified by Nora Foster. Five frogs were observed (incl. 2 females, 1 male) in a muskeg pond, probably breeding. Two specimens were deposited at the University of Alaska, Fairbanks. Liver and leg muscle tissue are in ultracold storage (AF 0010–11) and the carcasses are in 95% ethanol (UAF 1992–5). These specimens represent the first observation of this species within the state of Alaska. The nearest known populations of this species are from

a locality on Graham Island (North Queen Charlotte Island, British Columbia), 185 km SW, where they may be native, and at Eutsuk Lake (B. C.), 380 km SE, where they were introduced (Stebbins 1985, A Field Guide to Western Reptiles and Amphibians. Second Ed. Houghton Mifflin Co., Boston, 336 pp.). It is uncertain whether the Ketchikan population was introduced. Other species of herpetofauna with similar distributions in British Columbia (e.g., *Thamnophis elegans, Elgaria coerulea, Ascaphus truei*) occur in disjunct populations, notably at Kitimat and in the Skeena River (Stebbins, op. cit.). This species was previously placed in the genus *Hyla*.

Submitted by **DANA L. WATERS**, U. S. Fish and Wildlife Service, California Cooperative Fishery Research Unit, Humboldt State University, Arcata, California 95521, USA.

RANA CATESBEIANA (Bullfrog). USA: TENNESSEE: Warren Co: jct. Rts. 127 & 30. 27 May 1991. J. L. Miller and B. T. Miller (Tennessee Scientific Study Permit 418). Verified by D. E. Metter. Middle Tennessee State University (MTSU 38A). County record (Redmond 1985, A biogeographic study of amphibians in Tennessee, Doctoral Dissertation, Univ. Tennessee, Knoxville, 290 pp.).

Submitted by **BRIAN T. MILLER** and **JOYCE L. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

RANA SYLVATICA (Wood Frog). USA: WISCONSIN: Waukesha Co: Menomonee Falls Tamarack Swamp, Sec. 22, T8N, R20E. 22 October 1991. Donald M. Reed & Rachel E. Lang. Verified by G. S. Casper. Milwaukee Public Museum (MPM 25307). New county record (Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin, Milwaukee Public Museum, 205 pp.)

Submitted by **DONALD M. REDD** and **RACHEL E. LANG**, Environmental Planning Division, Southeastern Wisconsin Regional Planning Commission, P. O. Box 1607, Waukesha, Wisconsin 53187, USA.

RANA UTRICULARIA (Southern Leopard Frog). USA: TENNESSEE: Coffee Co: small spring-fed creek off Lyndell Bell Road, 2.9 km S Blantons Chapel Road. 5 May 1991. B. T. Miller (Tennessee Scientific Study Permit 418). Verified by D. E. Metter. Middle Tennessee State University (MTSU 35A). County record (Redmond 1985, A biogeographic study of amphibians in Tennessee, Doctoral Dissertation, Univ. Tennessee, Knoxville, 290 pp.).

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

SPEA BOMBIFRONS (Plains Spadefoot). USA: ARIZONA: Navajo Co: Partnership Tank on F. R. 88, 4.8 km E, 6.4 km N of Heber. 3 July 1988. J. Boundy. SJSU A3330–3332. Verified by D. L. Martin. Extends range ca. 60 km SW from NE Arizona Colorado Plateau range (Stebbins 1985, A Field Guide to Western Reptiles and Amphibians. Second Ed. Houghton Mifflin Co., Boston, 336 pp.).

Submitted by **JEFF BOUNDY**, 113 South U Street, Apt. 46, Lompoc, California 93436, USA.

SPEA BOMBIFRONS (Plains Spadefoot). USA: NEBRASKA: Nemaha Co: ca. 2 km S of Honey Creek on Nebr. Rt. 67, Sec. 3, T5N, R15E. 1 June 1991. K. B. Malmos & A. T. Holycross. University of Nebraska State Museum (UNSM 15059); Otoe Co: ca. 5 km SE of Nebraska City, Sec. 35, T8N, R14E. 1 June 1991. K. B. Malmos and A. T. Holycross. UNSM 15058. Both verified by John D. Lynch. New county records, fill significant gap in known distribution in Nebraska. (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **ANDREW T. HOLYCROSS** and **KEITH B. MALMOS**, Department of Biology, University of Nebraska at Omaha, Omaha, Nebraska 68182–0040, USA.

TESTUDINES

MACROCLEMYS TEMMINCKII (Alligator Snapping Turtle). KANSAS: Labette Co: Neosho River at Oswego. Summer 1886. W. S. Newlon. KU 197329. County record and earliest record for the state. Montgomery Co: Onion Creek, Sec. 9, T15E, R34S. 10 April 1986. C. D. Blex. KU 204668 (scute from carapace) and KU Color Slide 7406. County record. Both verified by Joseph T. Collins. The Labette County record had never been verified by voucher (Collins 1982, Amphibians and Reptiles in Kansas, Second ed., Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356) until I discovered its skull in a study collection at Washburn University, Topeka, Kansas.

Submitted by **KELLY J. IRWIN**, 2861 West 32nd Avenue, Manhattan, Kansas 66502, USA.

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). USA: GUAM (Mariana Islands): Mangilao Municipality: Mangilao. May 1991. Anonymous donation to DAWR. Verified by Thomas H. Fritts. Michael J. McCoid Private Collection (MJM 2956); deposited at USNM. First verified record for the island. This is the fourth adult individual seen by DAWR officials although there have been unverified sightings of 'hatchlings' in Mangilao. Other sightings include the Nimitz Hill area of Guam. The status of this turtle on Guam is uncertain. It is likely that this species has been repeatedly brought to Guam because high

numbers of military and civilian personnel are transferred to Guam from the mainland USA where this reptile is a commonly kept pet.

Submitted by **MICHAEL J. MCCOID**, Guam Department of Agriculture, Division of Aquatic and Wildlife Resources, P.O. Box 2950, Agana, Guam 96910.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). USA: COLORADO: Elbert Co: 5.6 km E & 0.8 km N Agate (SE 1/4, Sec. 3, T7S, R58W). June 1990. David Chiszar, Adam Chiszar & Kevin Fitzgerald. Verified by Todd Gleeson. University of Colorado Museum of Natural History (UCM Color Slides 61–62). First county record (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Department of Natural Resources, Denver, 131 pp.).

Submitted by **DAVID CHISZAR**, Department of Psychology and Museum of Natural History, and **HOBART M. SMITH**, Department of EPO Biology and Museum of Natural History, University of Colorado, Boulder, Colorado 80309, USA.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: GUAM (Mariana Islands): Mangilao Municipality: Lalo Mangilao. 11 March 1991. Anonymous donation to DAWR. Verified by Thomas H. Fritts. Michael J. McCoid Private Collection (MJM 2955); deposited at USNM. First verified record for the island. Individuals of this species have been observed in southern Guam in the Ugum, Namo, and Talofofo Rivers. Other sightings have been made in the Fena Valley Reservoir and the Agana Swamp. It is certain that the species is well established in Guam and should be expected in central and southern Guam where permanent and semi-permanent bodies of water exist. Nesting of this species has been observed along the Ugum River (G. Davis, DAWR, pers. comm.). Sightings of this species have also been made on Saipan (Commonwealth of the Northern Mariana Islands) in Lake Susupe, but it is unknown if this population is established. It is likely that this species was established on Guam due to releases or escapes from turtles present in the pet trade.

Submitted by **MICHAEL J. MCCOID**, Guam Department of Agriculture, Division of Aquatic and Wildlife Resources, P.O. Box 2950, Agana, Guam 96910.

LACERTILIA

FEYLINIA ELEGANS (NCN). CENTRAL AFRICAN REPUBLIC: Bouar. MNHN 1991-389; hill of Bangui: behind President's House. MNHN 1991-390; Zimba: 50 km downstream from Bangui. MNHN 1991-391 & 392. 27 January 1991 MNHN 1991-389; 6 March 1991. MNHN 1991-390; 23 May 1991. MNHN 1991-391 & 392. L. Chirio. Verified by Edouard R. Brygoo. First record for Central African Republic (Joger 1990. *In* Peters and Hutterer, eds. Vertebrates in the tropics. Museum Alexander Koenig, Bonn, 1990:85–102). Known before from N Zaïre (Brygoo and Roux-Esteve 1983, Bull. Mus. Natl. Hist. Nat., Paris, 4e Ser., 5, Section A, n° 1:307–341).

Submitted by **LAURENT CHIRIO**, 14 rue des Roses, F-06130 Grasse, France, and **IVAN INEICH**, Muséum National d'Histoire Naturelle, Laboratoire de Zoologie (Reptiles et Amphibiens), 25 rue Cuvier, F-75005 Paris, France.

OPHISAURUS ATTENUATUS (Slender Glass Lizard). USA: ILLINOIS: Jersey Co: Elsah, Sec. 17, Elsah Twp. 15 April 1962. Robert C. Brown. Southern Illinois University at Edwardsville Collection (SIUE 2537). Verified by Ralph W. Axtell. Lee Co: Green River Hunting Area. 19 April 1979. W. E. Southern. Northern Illinois University-H. D. Walley Collection (NIU-HDW 1449). Verified by Peter Merserve; 6 mi N Ohio, Thomas Ernot Farm. 12 July 1972. Michael D. Johnson. INHS 9842. Verified by Kevin S. Cummings. Madison Co: Melville, Sec. 29, Godfrey Twp. 4 May 1963. R. E. Adams. SIUE 2535. Verified by Ralph W. Axtell; Melville. 7 August 1964. R. E. Adams. SIUE 1536. Verified by Ralph W. Axtell. All the above represent new county records and/or extensions of range in Illinois. Will Co: Braidwood Dunes, Sec. 16, Reed Twp. 15 May 1987. John Levell. INHS 10779. This record helps substantiate a former record of this lizard from Custer Park, collected by Seymour Levy on 27 June 1956 (FMNH 75340). In addition, Smith (1961, Illinois Nat. Hist. Surv. Bull. 28(1):164) noted that this lizard was "more common in the dissected hills of Calhoun and Pike counties than elsewhere in the state," but he plotted only one locality for Calhoun County and none for Pike County on his distributional map. We herein report three specimens (UIMNH 50736–738) from near Pearl, Sec. 10, Pearl Twp., collected on 7 September 1951 by Robert Schroder. These specimens, verified by Christopher Philips, as well as a fourth (Western Illinois University Collection 14094 DOR) collected by Gordon R. Thurow from Napoleon Hollow Canyon, substantiate this lizard's presence in Pike County.

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115, USA and **JOHN LEVELL**, 1454 West Grace Street, Chicago, Illinois 60613, USA.

SERPENTES

AMBLYODIPSAS UNICOLOR (NCN). CENTRAL AFRICAN REPUBLIC: Bangui: found dead and dried on the parking lot of the French Embassy. 28 November 1990. Laurent Chirio. Verified by Hidetoshi Ota. MNHN 1991–325. A second specimen is present in MNHN collections; area of Gribingui river, south of Chad. 1921. Baudon. Verified by Hidetoshi Ota. MNHN 1921–27. First record for Central African Republic (Joger 1990. *In* Peters and Hutterer, eds. Vertebrates in the Tropics. Museum Alexander Koenig, Bonn, 1990:85–102). Known before from NE Zaire, SW Sudan and N Cameroon (Broadley 1971, Occ. Pap. Nat. Mus. Rhodesia B4(33):629–697).

Submitted by **IVAN INEICH**, Muséum National d'Histoire Naturelle, Laboratoire de Zoologie (Reptiles et Amphibiens), 25 rue Cuvier, F-75005 Paris, France, and **LAURENT CHIRIO**, 14 rue des Roses, F-06130 Grasse, France.

CROTALUS HORRIDUS (Timber Rattlesnake). USA: LOUISIANA: Washington Parish: between Ards and Fords Creeks, 5.6 km E Angie, crossing a gravel road 50 m off La. Rt. 438 (30°58'39"N, 89°45'31"E), Sec. 46, TIS, R14E. 2 October 1991. W. Glen Knight. Verified by Richard A. Seigel. Southeastern Louisiana University Vertebrate Museum (SLU-1004). First documented record for Washington Parish (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana State University Press, 300 pp.) and extends the Louisiana range ca. 96.5 km W Grangeville and 67.6 km N Mandeville.

Submitted by **WILLIAM I. LUTTERSCHMIDT**, Department of Zoology, University of Oklahoma, Norman, Oklahoma, 73019, USA.

DRYMARCHON CORAIS COUPERI (Eastern Indigo Snake). USA: FLORIDA: Pasco Co: north of Land-O-Lakes. 27 October 1990. Verified by Ronald A. Brandon. Four color slide vouchers, Southern Illinois University at Carbondale herpetology collection (SIUC R-2303). Fills a gap between Hernando, Sumter, Polk, Hillsborough, and Pinellas counties (Moler 1985, Distribution of the eastern indigo snake, *Drymarchon corais couperi*, in Florida. Herpetol. Rev. 16(2):37–38). On 5 November 1990, the Illinois Department of Conservation contacted me and asked if I would hold an eastern indigo snake they had confiscated. It had been

collected illegally in Florida and brought into Illinois. The collector provided information on the collection locality. On 8 November 1990, the IDOC issued me a temporary holding permit for the 68-inch male. On 2 January 1991, the IDOC issued a letter authorizing the snake's return to Florida. The snake was shipped back to Florida on 9 September 1991, where regional nongame biologist Nancy D. Joiner of the Florida Game and Fresh Water Fish Commission released the animal at its capture site. The fourth ventral scale anterior to the cloaca was clipped with two V-notches so that the snake may be identified if recaptured.

Submitted by **SCOTT R. BALLARD**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901–6501, USA.

ELAPHE OBSOLETA LINDHEIMERII (Texas Rat Snake). KANSAS: Barber Co: Sec. 13, T32S, R12W. 19 July 1983. J. T. Collins, K. J. Irwin, F. B. Cross, & R. E. Moss. KU 193399; Sec. 6, T35S, R12W. 14 May 1987. L. Miller & G. Trott. KU 207295; Sec.9, T35S, R14W. 19 May 1988. L. Miller. KU 211379; Cowley Co: 6.4 mi S & 6.4 mi E Winfield along Walnut River. 1 April 1978. L. Miller & M. Capron. KU 179036; Sec. 21, T32S, R3E. 24 May 1989. D. Phipps. KU 216190; Harper Co: 4.8 km W Anthony on Ks. Rt. 14. 25 May 1980. H. Guarisco. KU 186004; Kingman Co: 100 yards W jct. Rt. 14 & Rt. 42. 1 June 1990. C. Mammoliti. KU 216080; Sumner Co: 3 mi N Oxford. 23 September 1934. A. B. Leonard & W. S. Long. KU 18886; 8 km E Caldwell. 10 May 1986. L. Miller. KU 206231; Caldwell. 15 May 1986. L. Miller. KU 206232; Sec. 27, T34S, R3W. 8 June 1986. L. Miller. KU 206233; Caldwell.10 June 1986. L. Miller. KU 206234; Caldwell. 1 August 1986. L. Miller. KU 206400; Sec. 12, T35S, R3W. 8 October 1986. S. Schmidt. KU 206490. All verified by Joseph T. Collins. These 14 specimens all exhibited color and pattern variations typical of *E. o. lindheimerii*, as per Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston, 450 pp.). Two other specimens, one from Cowley County (KU 206174) and the other from Harper County (KU 22209), exhibited the color and pattern typical of the nominate race, and thus we consider this south-central Kansas population to be intergrades between the two subspecies.

Submitted by **KELLY J. IRWIN**, 2861 West 32nd Avenue, Manhattan, Kansas 66502, USA, **LARRY MILLER**, 920 SW 33rd Street, Topeka, Kansas 66611, USA, and **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

LAMPROPELTIS GETULA (Common Kingsnake). KANSAS: Morton Co: Cimarron National Grasslands, SE 1/4 Sec. 20, T34S, R43W. 12 May 1991. Robert L. Ball. KU 218810; Cimarron National Grasslands, NE 1/4 Sec. 16, T33S, R43W. 20 May 1991. Robert L. Ball. KU 218811. Verified by Joseph T. Collins. First records for county (Collins and Collins 1991, Reptiles and Amphibians of the Cimarron National Grasslands, Morton County, Kansas. U.S. Forest Serv. Publ. viii + 60 pp.).

Submitted by **ROBERT L. BALL**, HCR 2, Box 70, Brewster, Kansas 67732, USA.

LAMPROPELTIS TRIANGULUM AMAURA (Louisiana Milk Snake) USA: TEXAS: Rockwall Co: FM 550, ca. 4.8 km SW jct. FM 205 and I-30. 14 October 1991. Stacy Burnett. Verified by Jonathan A. Campbell. UTA R-30283. New county record. (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station, Texas, 434 pp.).

Submitted by **CLAY M. GARRETT**, Department of Herpetology, Dallas Zoo, 621 East Clarendon Drive, Dallas, Texas 75203, USA.

NATRICITERES OLIVACEA (Banded Olive Snake). CENTRAL AFRICAN REPUBLIC: Zimba: 50 km aval of Bangui. 30 December 1990. Laurent Chirio. Verified by Hidetoshi Ota. MNHN 1991–329. First record for Central African Republic (Joger 1990. *In* Peters and Hutterer, eds. Vertebrates in the Tropics. Museum Alexander Koenig, Bonn, 1990:85–102). Known before from far NW Zaïre, Zongo (Loveridge 1958, Bull. Mus. Comp. Zool. Harvard Univ. 119(1):25–49).

Submitted by **LAURENT CHIRIO**, 14 rue des Roses, F-06130 Grasse, France, and **IVAN INEICH**, Muséum National d'Histoire Naturelle, Laboratoire de Zoologie (Reptiles et Amphibiens), 25 rue Cuvier, F-75005 Paris, France.

REGINA SEPTEMVITTATA (Queen Snake). USA: TENNESSEE: Stewart Co: Land Between The Lakes (LBL), LBL Road 227, 2.0 km E LBL 100 (The Trace). 19 July 1991. Eugene Zirkle (Tennessee Permit 482). Verified by David H. Snyder, Austin Peay State University (APSU 4308). Female (750 mm TL, 580 mm SVL), with 14 near-full-term young (mean TL = 215.2 mm, SD = 32.9; mean SVL = 164.9 mm, SD = 28.5) in body cavity, found DOR in wooded area near Lake Barkley (impounded Cumberland River). First record for Stewart County and LBL (Snyder 1972, Amphibians and Reptiles of Land Between The Lakes, Tennessee Valley Authority, Golden Pond, Kentucky); extends known range in Tennessee 35 km NW of nearest known voucher (SW Montgomery County, APSU 3666), to W edge of the Highland Rim, and slightly NW of that shown by Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, 450 pp.).

Submitted by **A. FLOYD SCOTT** and **EUGENE ZIRKLE**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

SONORA SEMIANNULATA (Ground Snake). USA: NEW MEXICO: Socorro Co: DOR US Rt. 60, 7 km E jct. I-25, ca. 33 km NNE Socorro. 15 August 1984. Paul W. Hyder. Verified by Michael A. Williamson. University of New Mexico Museum of Southwestern Biology (MSB 51882). Extends range approximately 56 km NE from the central New Mexico population (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, 450 pp.).

Submitted by **PAUL W. HYDER**, Department of Biology, New Mexico State University, Las Cruces, New Mexico 88003, USA.

STORERIA DEKAYI (Brown Snake). USA: NEBRASKA: Webster Co: Wilma and Boyd Jones Native Prairie, Sec. 35, T1N, R10W. 13 July 1991. A. T. Holycross. Verified by John Lynch. University of Nebraska State Museum (UNSM 15014). New county record, extends range ca. 80 km W in Nebraska (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57). This specimen probably represents a population contiguous with Kansas populations to the south as opposed to Nebraska populations to the east.

Submitted by **ANDREW T. HOLYCROSS**, Department of Biology, University of Nebraska at Omaha, Omaha, Nebraska 68182–0040, USA.

THAMNOPHIS CYRTOPSIS (Blackneck Garter Snake). MÉXICO: SONORA: Caborca, Rancho La Bachata, 2 km NE of railroad station El Coyote. 27 July 1991. Sialia Karina Mellink. Centro Ecológico de Sonora (CES 670). Verified by C. H. Lowe. Four additional individuals were seen by E. Mellink on 29 July 1991. The site is a seasonal cattle tank, surrounded by mesquite (*Prosopis juliflora*) trees, close to a ranch house and cattle corral. The species was previously reported as "throughout Sonora (except extreme western part . . ." (Smith and Taylor 1945, An annotated checklist and key to the snakes of Mexico. U. S. Natl.

Mus. Bull. 187). The locality reported herein is in western Sonora, and is likely that of a small disjunct population, similar to those occurring in western Arizona (Lowe 1964, Amphibians and reptiles of Arizona. *In* Lowe (ed.), The Vertebrates of Arizona. Univ. Arizona Press, Tucson, pp. 153–174).

Submitted by **ERIC MELLINK**, Centro de Investigación Científica y Educación Superior de Ensenada, Apartado Postal 2732, Ensenada, Baja California, México.

THAMNOPHIS SIRTALIS ANNECTENS (Texas Garter Snake). USA: KANSAS: Meade Co: 2.4 km S Meade County State Park on Ks. Rt. 23. 13 June 1980. K. J. Irwin (KU 187499); 0.4 km E Meade County State Park dam, Sec. 24, T33S, R29W. 21 May 1986. K. J. Irwin (KU 206182); Meade County State Park headquarters. June 1991. M. Goldsberry (KU 218777). All verified by Joseph T. Collins. First records for state (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356). None of the specimens shows evidence of intergradation with *T. s. parietalis.*

Submitted by **KELLY J. IRWIN**, 2861 SW 32nd Avenue, Manhattan, Kansas 66502 USA.

TYPHLOPS HYPOMETHES (Culebrita Ciega Universitaria). PUERTO RICO: Isabela, Punto Sardina: 2.7 km E of intersection with PR 466. 20 November 1991. Manuel S. Leal. Verified by R. Thomas. Museum of Biology, University of Puerto Rico, Rio Piedras, UPRRP 5744 (adult female), and UPRRP 5745 (juvenile). First record for the NW part of the island; extends the range about 45 km W (airline) from the prior most western locality (7 km W Palmas Altas). This species was described by Hedges and Thomas (1991, Herpetologica 47(4):448–459).

Submitted by **MANUEL S. LEAL**, Department of Biology, P. O. Box 23360, University of Puerto Rico, Río Piedras, Puerto Rico 00931–3360.

Graptemys kohnii in the Pearl River: An Alternative Explanation

Jones et al. (1991) reported the Mississippi map turtle, *Graptemys kohnii* (*G. pseudogeographica kohnii* sensu Vogt 1978) from the Pearl River in the vicinity of Jackson, Mississippi. They attributed the presence of this species, previously found only in the Mississippi River Drainage in Mississippi, to introduction by release of captives. This is a plausible explanation, as hatchling *Graptemys* are commonly sold and kept as aquarium pets and equally commonly released into the nearest aquatic habitat when no longer wanted. However, on the basis of our field work during 1978 and 1979 we suggest an alternative explanation for the occurrence of this species in the Pearl River.

During the summers of 1978 and 1979 we conducted a turtle population study (McCoy and Vogt, in prep.) on the Pearl River near Georgetown, Copiah Co., Mississippi. We trapped turtles using non-selective techniques (Vogt 1980) during 21 days between 1 July and 13 August 1978, and 25 days between 10 June and 4 August 1979. A total of 716 turtles were taken in 1978 and 851 in 1979. Most of the turtles were marked and subsequently released at the original site of capture.

The natural turtle fauna of the Pearl River at the study site conslsts of 10 species. The seven most abundant (both years) were *Sternotherus carinatus, Pseudemys concinna, Trachemys scripta, Graptemys oculifera, G. pulchra, Apalone mutica,* and *A. spinifera. Macroclemys temminckii* was present in small numbers, and one or two specimens of *Chelydra serpentina* and *Sternotherus odoratus* were caught each year. In 1979 a single specimen of *G. kohnii* was taken, a subadult female (CM 95653),carapace length 58.7 mm , in its third year (from growth rings). The animal appeared healthy, and showed no signs of having been in captivity.

In April 1979, between the two trapping seasons, the most extensive flood in the history of the Pearl River occurred, surpassing even the great flood of 1874 (Edelen et al. 1986). Maximum discharge at the gauging station at Monticello, Mississippi, 64 river km below the study site was 3,424.3 m^3/sec, more than 60 times summer normal ($x = 56$ m^3/sec, 1978 and 1979 trap days combined). The river at the study site, usually 15-20 m wide at summer low water, was several kilometers out of banks.

At normal river levels tributaries of the Pearl River (Copiah Creek and Little Copiah Creek) approach Mississippi River tributaries (Bayou Pierre) within 3 km in central Copiah County. At maximum flood stage in April, 1979 these watersheds may have been in communication. We suggest that an explanation for the appearance of *Graptemys kohnii* in the 1979 samples, and an alternative explanation for the presence of the species in the Pearl River, is natural dispersal into the Pearl River from Mississippi River tributaries during the April 1979 flood.

Acknowledgments.—Field work was supported by the Netting Research Fund, Carnegie Museum of Natural History and the U. S. Fish and Wildlife Service (Contract No.14-16-0004-79-038). D. G. Cook, P. S. Freed, J. F. Jacobs, J. F. Norton, and M. J. Pappas assisted in the field. We thank the Mississippi Department of Wildlife, Fisheries and Parks for issuing collecting permits, the Jackson Office, U.S. Geological Survey for flood data, and the Rainey Family of Georgetown for their hospitality.

BOOK REVIEWS

A Field Guide to Reptiles and Amphibians of Eastern and Central North America, by Roger Conant and Joseph T. Collins. 1991. Houghton Mifflin Company, Boston, Massachusetts. Peterson Field Guide Series Number 12. Third edition. xviii + 450 pp., 48 color plates, 333 maps. Hardcover $24.95, Softcover $16.95.

What can one say about a field guide that has withstood the test of time? It is the best source of accurate identification of the amphibians and reptiles of eastern North America. This new

edition, like its predecessors, will inspire and educate those already committed to natural history and many who will become our future herpetologists. Accuracy, attention to detail, and the illustrations set this book apart from the other field guides on the market. In many respects the third edition is similar to the second, but it does contain some substantial differences.

The first paragraph of the introduction to the second and third editions identifies three groups for whom the book was written, professional herpetologists, herpetoculturists, and field naturalists. Accurate identification of amphibians and reptiles is central to the activities of these people. This field guide has become an overwhelming success because its primary focus is accurate identification. Almost anyone can take this book into the field and properly identify adults and juveniles of most species encountered.

The chapter sequence remains the same. A thorough introduction is followed by chapters on capture and transportation techniques and care in captivity. An important new contribution is the reminder in the beginning of the techniques chapter to check with state authorities for lists of protected species and laws regulating collecting. Many states have enacted laws that restrict collecting native species and owning certain others. This trend will likely continue. The chapter on snakebite was carefully rewritten under the direction of Drs. S. A. Minton and D. L. Hardy. There is a short but useful glossary, a completely revised list of general, regional, and state references, and an index that allows one to find any species by common, scientific, and many vernacular names. The latter is especially important for the layman.

Each species account follows a rigid format established in the first edition. The common name is given before the scientific name, and the number of the plate on which its illustration appears is noted. The range of adult body length is listed in inches and centimeters, followed by known maximum total length. Head-body length (snout-vent length, SVL) is also given for lizards, but not salamanders and snakes. The comment (p. 12) that lizards often possess shorter than normal tails due to partial regeneration is well taken, but salamanders and snakes often possess partial tails. SVL is a standard measure used in the scientific literature and this information should be provided for all appropriate groups.

The verbal descriptions are the most accurate of those in field guides currently on the market. Adults and juveniles, where appropriate, are included in the description. The habitat and some aspects of behavior are noted for most species. Additional notes on unique aspects of the biology of each species and preferred prey are provided in some cases. Similar species are listed with brief descriptions to allow accurate comparisons, and the geographic distribution is described and the corresponding map number indicated.

The second edition covered 331 species and 574 subspecies, whereas the third edition includes 379 species and 595 subspecies. The increase stems from three sources: new discoveries, systematic changes, and introduced species. Several new species have been discovered outright since 1975 (e.g., *Rana okaloosae*, Moler 1985; *Ophisaurus mimicus*, Palmer 1987; *Plethodon petraeus*, Wynn et al. 1988), cryptic species have been discovered in what were formerly single widespread species (13 species in the *Plethodon glutinosus* complex, Highton et al. 1989; *Ambystoma barbouri*, Kraus and Petranka 1989), and subspecies have been elevated to specific status (e.g., *Eurycea bislineata*, *E. cirrigera*, *E. wilderae*, Jacobs 1987; *Nerodia floridana*, Lawson 1987). Fourteen introduced species were described in the second edition compared to 27 in the third edition. Most have become established in southern Florida. Unfortunately, introduced species often adversely affect native species and communities. It remains to be seen if the amphibian and reptile introductions are benign.

A substantial number of taxonomic changes have occurred since the publication of the second edition. Most have been incorporated into this book, but some have not. For example, emydid turtles formerly lumped into the single genus *Chrysemys* are now in the genera *Chrysemys*, *Pseudemys*, and *Trachemys*, water snakes formerly in *Natrix* are now *Nerodia*, *Regina*, and *Clonophis*, and the spring peeper *Hyla crucifer* and the little grass frog *Limnaoedus ocularis* are now in the genus *Pseudacris*. Conant and Collins have rejected several proposed changes, such as dividing *Gopherus* into *Gopherus* and *Xerobates* for the gopher and desert tortoises, and *Scaphiopus* into *Scaphiopus* and *Spea* for the spadefoot toads. They reject outright the suggested synonymy of *Sternotherus* into *Kinosternon* for the musk turtles and *Thamnophis* into *Nerodia* for garter snakes. A substantial taxonomic modification above the generic level was the recent splitting of the large lizard family Iguanidae into eight families, following Frost and Etheridge (1989). Members of six of the families occur in eastern North America. Where are the explanations for these decisions? Readers unfamiliar with systematic herpetology will wonder why these names were changed. The authors missed an opportunity to educate the general public about the importance and dynamics of systematics. It would have taken only a few paragraphs, and it would have helped readers understand that names are not cast in stone.

Any reader familiar with the second edition will quickly see that many common names have been changed substantially. The new ones follow Collins (1990). Collins is a proponent of standardization of common names for North American amphibians and reptiles. Unfortunately for the herpetological community and the reader, some of the names used are controversial and will not be used by everyone. For example, the red-bellied turtle (*Pseudemys rubriventris*) is now the redbelly turtle, the plains black-headed snake (*Tantilla nigriceps*) is the plains blackhead

snake, and the shovel-nosed salamander (*Leurognathus marmoratus*) is the shovelnose salamander. On first glance hyphenated names ending in -ed have been changed to single names with the ending dropped. However, we still find black-striped snake, broad-banded copperhead, red-eared slider, bird-voiced treefrog, and broken-striped newt. One has to wonder what criteria were used to select these standard common names. Unlike bird watchers, amateur and professional herpetologists have long used scientific names instead of common names. Because of the controversy, readers should make their own choice of whether to use scientific names, the common names in the third edition, or the common names in the second edition. It remains to be seen whether the controversy will be settled by the time the fourth edition appears.

Tom Johnson followed in the footsteps of Isabelle Hunt Conant by providing accurate and beautiful illustrations of many species. These include many not seen in the second edition. He hand-colored all of the previously black and white plates and provided several new ones. He deserves our accolades for his important contributions to this book.

The second edition contained a plate on capture and handling techniques and one on first aid for snakebite. The first plate now appears in the techniques chapter, and the second one was omitted. Thus, the 48 plates found in the center signature contain color illustrations of most of the species and subspecies covered in the text. Excellent drawings of tadpoles of 14 species of frogs appear on pages 348-353. I hope this sampling will tantalize some readers to learn more about this fascinating life history stage. Perhaps Tom Johnson can provide illustrations of aquatic salamander larvae in the next edition of the book.

As Conant and Collins point out (p. 9), accurate identification of many of the subspecies of amphibians and reptiles is quite possible. Conant resolved the question of whether to include them or not in the first edition. Those subspecies that could be distinguished visually without a microscope, recourse to scale counts, internal anatomy, or sophisticated laboratory techniques were illustrated in the plates. This was an important decision, for it increased the utility of the field guide. It also made readers pay more attention to geographic variation in these animals. Treating subspecies in the text is another matter, but was resolved by including each of those illustrated in the color plates under a separate main entry. Despite the discussion of the subspecies category, clinal variation, and some of the problems with delineation of this taxon, separate main entries have, in my experience, led amateurs to equate subspecies with species. On numerous occasions I have found myself explaining that subspecies are races of the same species and members of those subspecies can freely interbreed. In one instance an amateur herpetologist collecting salamanders for someone conducting a reproductive study in a zone of overlap retained only those specimens that looked like the subspecies in which the researcher said she was interested. The other phenotype, and presumably some intergrades, were not collected. When queried, the collector found it difficult to understand the concept of population variation, especially in areas of contact between subspecies. The subspecies was in his mind a separate entity. I do not know how widespread this problem is, but I wonder if there may be a way of arranging the descriptions in the text of the field guide so that there is little confusion over the relationship between subspecies and species.

A difficult and largely thankless task in the preparation of a field guide is the construction of distribution maps. Collins took over this job for the third edition of this book and spent several years accumulating information. The 333 shaded range maps are reasonably accurate for most species. I understand from the authors that several errors have been brought to their attention. They and the book's readers should realize, however, that it is nearly impossible to make all shaded range maps completely error-free. These maps reflect the philosophy of their maker: areas without confirmation (museum specimens or slides) are unshaded to stimulate collectors to obtain scientific vouchers to prove him wrong. Hence, maps of riverine species (e.g., *Graptemys kohnii*, *Apalone mutica*) are shown with shaded fingers instead of illustrating broad sweeps of geography where they may occur. There are also more open areas in the distribution maps of the third edition than in the second edition (see for example *Necturus maculosus* and *Elaphe guttata*). The subspecific problem rears its head here as in the text (see above). Most maps containing subspecies are shown with distinct lines indicating ranges abutting those of adjacent subspecies. Only a few, such as the maps for *Agkistrodon contortrix* and *Desmognathus fuscus*, show overlap zones. Illustrating contact zones with overlapping shading would help reduce some of the misunderstandings about subspecies.

The book is well-written, well-bound for long term wear, and attractive. I found only a few minor errors and problems, and no misspellings. Figure 20 refers to *C. texana* when the text uses *Cophosaurus texanus*. The family for *Rhinophrynus dorsalis* was left out of both editions, whereas all other species fall under a family heading. In the Index, under "moccasin," one finds "see cottonheads and coppermouths." Names for turtle scutes on the inside of the front cover reflects outdated terminology; nuchal should be cervical and costal should be pleural (see Ernst and Barbour 1989). The illustrations in Plate 3 are considerably darker in my hardbound copy than in my softbound copy. In the review copy Plate 3 has a green spot on the plastron of *Emydoidea blandingii* and on the carapace of *Kinosternon subrubrum*.

It should be clear from this review that a few improvements can be made in this book. I remain concerned about some of the common names, and how difficult it is for books such as these to convey to the general public the concepts and dynamics inherent in the fields of systematics and taxonomy. I also fear that some readers will come away thinking that there is little left to do with North American species, when in fact there are huge information gaps.

These concerns not withstanding, I highly recommend this book to anyone seriously and even casually interested in the amphibians and reptiles of eastern North America. Buy a copy for yourself and additional copies for friends interested in natural history. The price is reasonable, especially for a softbound copy. Obviously much can be said for the best field guide on the market.

Richmond, Virginia 23173, USA.

A Field Guide to Reptiles and Amphibians of Eastern and Central North America.

Because of its enormous importance to herpetologists and naturalists alike, the editors of *Herpetological Review* thought it advisable to have the new edition of Roger Conant's famous *Field Guide* reviewed by two people with somewhat different approaches to herpetology. Joseph Mitchell, the author of the preceding in-depth review, emphasizes natural history and ecology in his research; my own field is systematics, with an emphasis on biochemical techniques.

Mitchell has done a fine job of describing the contents of this updated field guide, and he has provided many useful comments and criticisms, all of which I agree with. Much of what I would have written in my review therefore has been said already. I will not repeat the points Mitchell has covered, except to emphasize topics that I feel are particularly important.

The third edition of Conant's field guide, updated with the help of his new co-author, Joseph T. Collins, follows essentially the format of the previous editions. There are several changes, however. Some of these are improvements, some are not.

The most obvious improvement, and undoubtedly the major reason for producing a new edition, is the updating of species diagnoses and taxonomy to reflect the results of systematic work conducted since the second edition appeared in 1975. The 1975 edition was published just as biochemical techniques were beginning to be used in the analysis of geographic variation and species boundaries in reptiles and amphibians, and the ever-expanding use of biochemistry in the intervening 16 years has demonstrated the existence of numerous cryptic species. This is particularly true among the salamanders. In the second edition, there were 72 recognized species of salamanders. By the third edition the total is 98, of which only a few (e.g., *Plethodon petraeus*) were newly discovered since 1975. Others were deleted from the third edition because they turned out to be parthenogenetic hybrids (*Eurycea latitans* and *E. troglodytes*) or synonymous with another species (*Plethodon longicrus* with *P. yonahlossee*). Significantly, 27 of the newly included species (27.6% of the total) were identified largely on the basis of biochemical methodologies. This upward trend in the number of identified species continues and this third edition soon will be out of date. I personally am aware of data suggesting that there are probably further unrecognized species of *Siren*, *Pseudobranchus*, *Desmognathus*, *Aneides*, and *Eurycea*. Nothing, of course, can be done about this; the authors cannot document future knowledge.

The use of biochemical techniques has allowed us to better understand the diversity of reptiles and amphibians. It has also allowed us to recognize units in nature, including species, that are only identifiable using biochemical characters. This, although it is a boon to herpetology as a whole, is a problem when one is trying to produce a guide to field identification. Most biochemical techniques cannot be used in the field, and in any case such techniques are not available to the vast majority of potential users of the guide. The authors have handled this problem in a variety of ways. In some cases (e.g., *Desmognathus santeetlah* and *D. fuscus*) recognition of the appropriate units in nature has allowed for the identification of minor morphological differences that were previously unrecognized. In these cases the species are listed separately using the standard format. In cases in which species are morphologically indistinguishable, the authors are inconsistent in their format. For example, *Ambystoma barbouri* and *A. texanum* are morphologically identical, but they are listed separately. Alternatively, *Plethodon glutinosus* recently has been

divided into 13 essentially morphologically indistinguishable species. Unlike *A. barbouri*, these are listed under the single heading "*Plethodon glutinosus* complex."

Problems with the way species, subspecies, and species complexes have been presented in this field guide are discussed at length in the preceding review. I would, however, like to add my voice to Mitchell's in his criticism of this format. Subspecies are sometimes presented as distinct entries apparently with the same "weight" as species while others are simply listed within the species entry. Hence, to the layman some of the subspecies come across as somehow more "important" than others. Admittedly, Conant and Collins explain their formatting criteria in the introduction to the book (readily identifiable subspecies are accorded separate accounts, more obscure ones are listed within species accounts), but unfortunately very few users of the guide will read the introduction (I probably never would have read it if I had not been asked to do this review).

The range maps in the third edition have been updated and much improved. The edges of the distributions of many species are much more dissected than in the second edition, and this undoubtedly reflects an improved knowledge of exact distribution patterns. In some cases, however, distributional margins appear to have been drawn to reflect accurate knowledge where such knowledge does not exist. For example, several species (e.g., *Rana septentrionalis* and *Thamnophis sirtalis*) have ranges that extend northward into northern Ontario and Quebec where herpetological reconnaissance has been minimal. Yet these margins are drawn as wavy lines suggestive of great accuracy. The current knowledge of distribution patterns in this part of the world would be better displayed as straight lines (which better suggest a lack of knowledge), or perhaps with a series of question marks.

Something that I think would be very useful to many users of this field guide would be the inclusion of at least minimal literature citations. The example Mitchell cited in his review was the division of the Iguanidae into multiple families. This is liable to be very confusing to many users, but this confusion would be cleared up by the inclusion of a citation to Frost and Etheridge (1989). Another example can be seen in *Acris crepitans*. Conant and Collins accept the subspecies *A. c. paludicola* for populations in southeastern Texas and southwestern Louisiana although Dundee and Rossman (1989) were unaware of the use of the name for Louisiana populations. I think the book would be much improved if statements such as "subspecific taxonomy according to . . ." or "familial designations according to . . ." were included. A single citation in each case would be sufficient.

One of Mitchell's major criticisms, and one I wish to emphasize as well, is the modification of the common names in the third edition of the field guide to follow Collins (1990). I have no problem with standardizing common names but I do not understand why the "standard" common name chosen in many cases differs from the one most commonly used for a given species. Why, to use Mitchell's example, change "red-bellied turtle" to "redbelly turtle"? "Redbelly" sounds like a blues musician. I hesitate to suggest what the "blackhead" in "blackhead snake" brings to mind. Neither Mitchell nor I are by any means the first to make this complaint (e.g., Huheey 1978; Rossman et al. 1978).

I have discussed a number of criticisms of the new edition of the *Field Guide to the Reptiles and Amphibians*, but in truth none of these criticisms is really very important. The book is excellent and I cannot imagine that anyone even remotely interested in herpetology or in natural history in general can do without a copy. It, like the previous two editions, is head and shoulders above any of the other amphibian and reptile guides currently on the market.

PUBLICATIONS RECEIVED

Annotated Checklist and Bibliography of Amphibians and Reptiles of Tennessee (1835 through 1989), by William H. Redmond, Arthur C. Echternacht, and A. Floyd Scott. 1990. Miscellaneous Publications of The Center for Field Biology, Austin Peay State University, Number 4. Center for Field Biology Publications, Department of Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA. (no ISBN No.) $4 + $1 s&h. iii + 173 pp.

A review and update of information on distributions, taxonomy, and habitats of Tennessee's herpetofauna, plus an extensive (1124 titles) annotated list of literature dealing with herpetology in the state.

ERRATUM

In the first complete paragraph on p. 6 of Ritke and Babb (199l. Herpetol. Rev. 22(1):5-6,8) the third sentence should read: "These frogs may have been waiting to ambush prey; we once observed (22 Oct., 1343 h, 27.3°C) male #2 leap ca. 0.3 m from his resting position and consume a prey item." This correction in the time of observation of feeding behavior by *Hyla chrysoscelis* is significant because it indicates that a nocturnal species such as the gray treefrog may feed during the day to facilitate the production of energy reserves before the onset of winter dormancy.

PUBLICATIONS OF THE

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

SOCIETY PUBLICATIONS may be purchased from:

Dr. Robert D. Aldridge, Publications Secretary,
Department of Biology, St. Louis University,
St. Louis, Missouri 63103, USA.
(telephone: area code 314, 658-3900 or 658-3916;
fax: area code 314, 658-3117).

Prices are effective through December 1992. Please make checks payable to "SSAR." Shipments sent at customer's risk; however, packages can be insured at cost (see below). Overseas customers must make payment in USA funds using a draft drawn on American banks (include an additional amount to cover bank conversion charges) or by International Money Order. All persons may charge to MasterCard or VISA (in which case account number and expiration date must be provided); for those paying by credit card, a 5% bank charge will be added to your credit-card account. Items marked "out-of-print" are no longer available.

Shipping and Handling Costs

Shipments inside the USA: Shipping and handling costs are in addition to the price of publications. Add an amount for shipping of the first item ($2.00 for a book costing $10.00 or more **or** $1.00 if the item costs less than $10.00) plus an amount for any additional items ($1.00 each for books costing over $10.00 and $0.50 for each item costing less than $10.00).

Shipments outside the USA: Determine the cost for shipments inside USA (above) and then **add** 4% of the total cost of the order.

Large prints (marked *): For shipments inside the USA, add $3.00 for any quantity; outside the USA, instead add $7.00 for any quantity.

Insurance costs: For shipments inside the USA, add $1.00 for each $50.00 value of order; outside the USA, instead add $2.00 for each $50.00 of value.

CONTRIBUTIONS TO HERPETOLOGY

Book-length monographs, comprising taxonomic revisions, results of symposia, and other major works. Prepublication discount to Society members.

No. 1. *Reproductive Biology and Diseases of Captive Reptiles*, by James B. Murphy and Joseph T. Collins (eds.). 1980. Results of a Society-sponsored symposium, including papers by 37 leading specialists. 287 p., illus. Paperbound $26.00.

No. 2. *The Turtles of Venezuela*, by Peter C. H. Pritchard and Pedro Trebbau. 1984. An exhaustive natural history covering half of the turtle species of South America, with worldwide checklist of turtle genera and species. 414 p., 48 color plates (25 watercolor portraits by Giorgio Voltolina and 165 photographs of turtles and habitats) measuring 8 1/2 x 11 inches, keys, 16 maps. Regular edition, clothbound $45.00; patron's edition, two leatherbound volumes in cloth-covered box, signed and numbered by authors and artist $300.00; set of 25 color prints of turtle portraits, on heavy paper stock and in protective wrapper $30.00.

No. 3. *Introduction to the Herpetofauna of Costa Rica / Introducción a la Herpetofauna de Costa Rica*, by Jay M. Savage and Jaime Villa R. 1986. Bilingual edition in English and Spanish, with distribution checklist, bibliographies, and extensive illustrated keys. 220 p., one color plate, map. Clothbound $30.00.

No. 4. *Studies on Chinese Salamanders*, by Ermi Zhao, Qixiong Hu, Yaoming Jiang, and Yuhua Yang. 1988. Evolutionary review of all Chinese species with keys, diagnostic figures, and distribution maps. 80 p., 7 plates (including 10 color photographs of salamanders and habitats). Clothbound $12.00.

No. 5. *Contributions to the History of Herpetology*, by Kraig Adler, John S. Applegarth, and Ronald Altig. 1989. Biographies of 152 prominent herpetologists (with portraits and signatures), index to 2500 authors in taxonomic herpetology, and academic lineages of 1450 herpetologists. International coverage. 202 p., 148 photographs, 1 color plate. Clothbound $20.00.

No. 6. *Snakes of the* Agkistrodon *Complex: A Monographic Review*, by Howard K. Gloyd and Roger Conant. 1990. Comprehensive treatment of 33 taxa of pitvipers included in four genera: *Agkistrodon* of Asia and America, *Calloselasma* of Southeast Asia and Java, *Deinagkistrodon* of China, and *Hypnale* of India and Sri Lanka. Also includes nine supplementary chapters by leading specialists. 620 p., 33 color plates (247 photographs of snakes and habitats), 20 uncolored plates, 60 text figures, checklist and keys, 6 charts, 28 maps. Clothbound $75.00; separate set of the 247 color photographs of snakes and habitats (in 32 plates), in protective wrapper $30.00.

No. 7. *The Snakes of Iran*, by Mahmoud Latifi. 1991. Review of the 60 species of Iranian snakes, covering general biology, venoms, and snake bite. Appendix and supplemental bibliography by Alan E. Leviton and George R. Zug. 167 p., 22 color plates of snakes (66 figures), 2 color relief maps, 44 species range maps. Clothbound $22.00.

No. 8. *Handbook of Middle East Amphibians and Reptiles*, by Alan E. Leviton, Steven C. Anderson, Kraig Adler, and Sherman A. Minton. 1992. Checklist, key, and identification manual covering 150 species and subspecies found in region from Turkish border south through the Arabian Peninsula (including Bahrain, Qatar, and United Arab Emirates) and the Arabian (Persian) Gulf. Chapters on venomous snakes and snake bite treatment plus extensive bibliography; appendix by John E. Simmons on collecting and preserving techniques. About 250 p., 32 color plates (220 photographs), maps, text figures. Clothbound $28.00.

FACSIMILE REPRINTS IN HERPETOLOGY

Exact reprints of classic and important books and papers. Most titles have extensive new introductions by leading authorities. Prepublication discount to Society members.

ANDERSON, J. 1896. *Contribution to the Herpetology of Arabia.* Introduction and new checklist of Arabian amphibians and reptiles by Alan E. Leviton and Michele L. Aldrich. 160 p., illus. (one plate in color), map. Clothbound $25.00.

BELL, T. 1842–1843. *Herpetology of the "Beagle."* Part 5 of Charles Darwin's classic, "Zoology of the Voyage of H.M.S. Beagle," containing descriptions of amphibians and reptiles collected on the expedition. Introduction by Roberto Donoso-Barros. 100 p., 20 plates (measuring 8½ x 11 inches), map. Paperbound $13.00, clothbound $18.00.

BOJANUS, L. H. 1819–1821. *Anatome Testudinis Europaeae.* The standard atlas of turtle anatomy. Introduction by Alfred Sherwood Romer. 200 p., 40 foldout plates. Out-of-print.

BOULENGER, G. A. 1877–1920. *Contributions to American Herpetology.* A series of collected papers from various journals covering North, Central, and South American species; complete in 18 parts totalling 880 p., numerous illustrations. Paperbound.

Table of Contents: Parts 1–10, 1877–1897, introduction by James C. Battersby. 20 p., $2.00.

Part 1: 1877–1881, 6 papers, 32 p., $4.00.
2: 1882–1883, 12 papers, 48 p., $4.00
3: 1884–1885, 10 papers, 44 p., $4.00.
4: 1886–1887, 10 papers, 56 p., $4.00.
5: 1888, 13 papers, 32 p., $4.00.
6: 1889–1890, 10 papers, 48 p., $4.00.
7: 1891–1893, 11 papers, 44 p., $4.00.
8: 1894, 5 papers, 40 p., $4.00.
9: 1895–1896, 11 papers, 52 p., $4.00.
10: 1897, 2 papers, 56 p., $4.00.

Table of Contents: Parts 11–18, 1898–1920, 12 p. $2.00.

Part 11: 1898, 4 papers, 52 p., $4.00.
12: 1899–1900, 9 papers, 48 p., $4.00.
13: 1901–1902, 7 papers, 34 p., $4.00.
14: 1903–1904, 8 papers, 28 p., $4.00.
15: 1905–1911, 12 papers, 42 p., $4.00.
16: 1912–1913, 6 papers, 46 p., $4.00.
17: 1914–1919, 8 papers, 38 p., $4.00.
18: 1920, 3 papers, 64 p., $4.00.

Index, 44 p., $2.00.

Complete set: 18 parts plus Index and both Tables of Contents, in parts as issued, $55.00.

BULLETIN OF THE ANTIVENIN INSTITUTE OF AMERICA. Volumes 1–5, 1927–1932. Complete set of an important journal devoted to venomology and to the taxonomy, biology, and distribution of snakes, lizards, salamanders, and crocodilians. Introduction by Sherman A. Minton. 575 p., 163 photographs, maps, index. Out-of-print.

CAMP, C. L. 1923. *Classification of the Lizards.* The foundation of modern lizard systematics. New preface by the author and an introduction by Garth Underwood. 220 p., 112 figures, index. Out-of-print.

CHANG, M. L. Y. 1936. *Amphibiens Urodèles de la Chine.* The classic work on Chinese salamanders, with a new checklist by Arden H. Brame. 168 p., illus., 5 plates. Out-of-print.

COPE, E. D. 1864. *Papers on the Higher Classification of Frogs.* Reprinted from Proceedings of the Academy of Natural Sciences of Philadelphia and Natural History Review. 32 p. Paperbound $3.00.

COPE, E. D. 1871. *Catalogue of Batrachia and Reptilia Obtained by McNiel in Nicaragua; Catalogue of Reptilia and Batrachia Obtained by Maynard in Florida.* 8 p. Paperbound $1.00.

COPE, E. D. 1892. *The Osteology of the Lacertilia.* An important contribution to lizard anatomy, reprinted from Proceedings of the American Philosophical Society. 44 p., 6 plates. Paperbound $4.00.

COWLES, R. B. and C. M. BOGERT. 1944. *A Preliminary Study of the Thermal Requirements of Desert Reptiles.* The foundation of thermoregulation biology, with extensive review of recent studies by F. Harvey Pough. Reprinted from Bulletin of American Museum of Natural History. 52 p., 11 plates. Paperbound $5.00.

DUNN, E. R. 1926. *Salamanders of the Family Plethodontidae.* A recognized classic treatment of the plethodontid salamanders, including tropical and European species. Introductions by David B. Wake and Arden H. Brame. 480 p., illus., 3 plates, 86 maps, index. Paperbound $20.00.

ESCHSCHOLTZ, F. 1829–1833. *Zoologischer Atlas* (herpetological sections). Descriptions of new reptiles and amphibians from California and the Pacific. Introduction by Kraig Adler. 32 p., 4 plates (measuring 8½ x 11 inches). Paperbound $3.00.

ESPADA, M. JIMÉNEZ DE LA. 1875. *Vertebrados del Viaje al Pacifico: Batracios.* Major taxonomic work on South American frogs. Introduction by Jay M. Savage. 208 p., 6 plates, maps. Clothbound $20.00.

FITZINGER, L. J. 1843. *Systema Reptilium.* An important nomenclatural landmark for herpetology, including Amphibia as well as reptiles; world-wide in scope. Introduction by Robert Mertens. 128 p., index. Paperbound $15.00.

GLOYD, H. K. 1940. *The Rattlesnakes, Genera* Sistrurus *and* Crotalus. Introduction and new checklist by Hobart M. Smith and Herbert M. Harris. 300 p., plus 31 plates of photographs, index. Out-of-print.

GRAY, J. E. 1825. *A Synopsis of the Genera of Reptiles and Amphibia.* Reprinted from Annals of Philosophy. 32 p. Paperbound $3.00.

GRAY, J. E. 1831–1844. *Zoological Miscellany.* A privately printed journal, devoted mostly to descriptions of amphibians, reptiles, and birds from throughout the world. Introduction by Arnold G. Kluge. 86 p., 4 plates. Paperbound $6.00, clothbound $10.00.

GÜNTHER, A. 1885–1902. *Biologia Centrali-Americana. Reptilia and Batrachia.* The standard work on Middle American herpetology with 76 full-page plates measuring 8½ x 11 inches (12 in color). Introductions by Hobart M. Smith, A. E. Gunther, and Kraig Adler. 575 p., photographs, maps. Clothbound $50.00; separate set of the 12 color plates, in protective wrapper $18.00.

HOLBROOK, J. E. 1842. *North American Herpetology.* Five volumes bound in one. The classic work by the father of North American herpetology. Exact facsimile of the definitive second edition, including all 147 plates, measuring 8½ x 11 inches (20 reproduced in full color). Introduction and checklists by Richard and Patricia Worthington and by Kraig Adler. 1032 p. Leatherbound patron's edition, out-of-print; regular edition, clothbound $60.00.

JUNIOR SOCIETY OF NATURAL SCIENCES (CINCINNATI, OHIO). 1930–1932. Herpetological papers from the society's Proceedings, with articles by Weller, Walker, Dury, and others. 56 p. Paperbound $3.00.

KIRTLAND, J. P. 1838. *Zoology of Ohio* (herpetological portion). 8 p. Paperbound $1.00.

LECONTE, J. E. 1824–1828. *Three Papers on Amphibians,* from the Annals of the Lyceum of Natural History, New York. 16 p. Paperbound $2.00.

LINNAEUS, C. 1766–1771. *Systema Naturae* (ed. 12) and *Mantissa Plantarum* (herpetological portions from both). 56 p. Introduction by Kraig Adler. Out-of-print.

LOVERIDGE, A. 1946. *Reptiles [and Amphibians] of the Pacific*. The standard review of the herpetofauna of the Pacific region including Australia and extending from Indonesia to Hawaii and the Galápagos Islands. 271 p., 7 plates, 1 double-page map, index. Out-of-print.

McILHENNY, E. A. 1935. *The Alligator's Life History*. The most complete natural history of the American alligator. Introduction by Archie Carr and a review of recent literature by Jeffrey W. Lang. 125 p., 18 photographs and a portrait. Clothbound $20.00.

McLAIN, R. B. 1899. *Contributions to North American Herpetology*. Three privately printed papers containing important distributional records and the description of a new form. 28 p., index. Paperbound $2.00.

ORBIGNY, A. D' [and G. BIBRON]. 1847. *Voyage dans l'Amérique Méridionale*. This extract comprises the complete section on reptiles and amphibians from this voyage to South America. 14 p., 9 plates measuring 8 1/2 x 11 inches. $3.00.

RAFINESQUE, C. S. 1820. *Annals of Nature* (herpetological and ichthyological sections), 4 p. Paperbound $1.00.

RAFINESQUE, C. S. 1822. *On Two New Salamanders of Kentucky*. 2 p. Paperbound $1.00.

RAFINESQUE, C. S. 1832–1833. *Five Herpetological Papers from the Atlantic Journal*. 4 p. Paperbound $1.00.

SOWERBY, J. DEC., E. LEAR, and J. E. GRAY. 1872. *Tortoises, Terrapins, and Turtles Drawn From Life*. The finest atlas of turtle illustrations ever produced. Introduction by Ernest E. Williams. 26 p., 61 full-page plates (measuring 8 1/2 x 11 inches). Clothbound $25.00.

SPIX, J. B. VON and J. G. WAGLER. 1824–1825. *Herpetology of Brazil*. The most comprehensive and important early survey of Brazilian herpetology. Introduction by P. E. Vanzolini. 400 p., 98 plates, one in color (each measuring 8 1/2 x 11 inches), map. Clothbound $36.00.

TROSCHEL, F. H. 1850 [1852]. Cophosaurus texanus, *neue Eidechsengattung aus Texas*. 8 p. Paperbound $1.00.

TSCHUDI, J. J. VON. 1838. *Classification der Batrachier*. A major work in systematic herpetology, with introduction by Robert Mertens. 118 p., 6 plates. Paperbound $18.00.

TSCHUDI, J. J. VON. 1845. *Reptilium Conspectus*. Descriptions of new reptiles and amphibians from Peru. 24 p. Paperbound $2.00.

VANDENBURGH, J. 1895–1896. *Herpetology of Lower California*. A review of the herpetology of Baja California, Mexico (collected papers). 101 p., 11 plates, index. Paperbound $8.00.

WIEGMANN, A. F. A. 1834. *Herpetologia Mexicana*. Introduction by Edward H. Taylor. 66 p., 10 plates (folio, measuring 10 x 14 inches). Out-of-print.

WILCOX, E. V. 1891. *Notes on Ohio Batrachians*. 3 p. Paperbound $1.00.

WILLISTON, S. W. 1925. *Osteology of the Reptiles*. Covers living and extinct forms, with introduction by Claude W. Hibbard. 304 p., 191 text figures, index. Out-of-print.

WRIGHT, A. H. and A. A. WRIGHT. 1962. *Handbook of Snakes of the United States and Canada, Volume 3, Bibliography*. Out-of-print since about 1969, this cross-indexed bibliography is a necessary companion to Volumes 1 and 2. 187 p. Clothbound $18.00.

RECENT HERPETOLOGICAL LITERATURE

A comprehensive listing of titles and citations, with authors' addresses. Prior to 1983 these lists were published in *Herpetological Review*. Paperbound, as issued; series now suspended.

No. 1 (1983), 66 p., $3.00; no. 2 (1984), 44 p., $3.00.

HERPETOLOGICAL REVIEW AND H.I.S.S. PUBLICATIONS

The Society's official newsletter, international in coverage. In addition to news notes and feature articles, regular departments include regional societies, techniques, husbandry, life history, geographic distribution, and book reviews. Issued quarterly as part of Society membership or separately by subscription. All numbers are paperbound as issued and measure 8 1/2 x 11 inches. In 1973, publications of the Herpetological Information Search Systems *(News-Journal* and *Titles and Reviews)* were substituted for *Herpetological Review*; content and format are the same.

Volume 1 (1967–1969), numbers 1–9, $4.00 per number.

Volumes 2–22 (1970–1991), four numbers in each volume, $4.00 per number.

The following numbers are out-of-print and *no longer available*: Volume 1 (number 7), 3(2), 4(1), 5(1, 2), 6(1, 2, 4), 7(3, 4), and 10(2).

Cumulative Index for Volumes 1–7 (1967–1976), 60 pages, $4.00.

Cumulative Index for Volumes 1–17 (1967–1986), 90 pages, $7.00.

H.I.S.S. Publications: News-Journal, volume 1, numbers 1–6, and Titles and Reviews, volume 1, numbers 1–2 (all of 1973–1974), complete set, $10.00.

Index to Geographic Distribution Records for Volumes 1–17 (1967–1986), including H.I.S.S. publications, 44 pages, $5.00.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

Loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Issued by subscription. Individual accounts are not sold separately.

CATALOGUE ACCOUNTS:

Complete set: Numbers 1–505, $190.00.

Partial sets: Numbers 1–190, $60.00.
Numbers 191–410, $70.00.
Numbers 411–505, $60.00.

INDEX TO ACCOUNTS 1–400: Cross-referenced, 64 pages, $5.00.

IMPRINTED POST BINDER: $25.00. (Note: One binder holds about 200 accounts.)

SYSTEMATIC TABS: Ten printed tabs for binder, such as "Class Amphibia," "Order Caudata," etc., $5.00 per set.

JOURNAL OF HERPETOLOGY

The Society's official scientific journal, international in scope. Issued quarterly as part of Society membership. All numbers are paperbound as issued, measuring 7 x 10 inches.

Volume 1 (1968), numbers 1–4 combined.

Volumes 2–5 (1968–1971), numbers 1–2 and 3–4 combined, $6.00 per double number.

Volume 6 (1972), numbers 1, 2, and double number 3–4.

Volumes 7–25 (1973–1991), four numbers in each volume, $6.00 per single number.

The following volumes and numbers are out-of-print and are *no longer available*: Volume 1, 2, 3 (double number 1–2), 4 (double number 3–4), 5, 6, 7(1), 8(1), 9(1, 2, 4), 11(4), and 12(1, 2).

Cumulative Index for Volumes 1–10 (1968–1976), 72 pages, $7.00.

HERPETOLOGICAL CIRCULARS

Miscellaneous publications of general interest to the herpetological community. All numbers are paperbound, as issued. Prepublication discount to Society members.

No. 1. *A Guide to Preservation Techniques for Amphibians and Reptiles* by George R. Pisani. 1973. 22 p., illus. $3.00.

No. 2. *Guía de Técnicas de Preservación de Anfibios y Reptiles* por George R. Pisani y Jaime Villa. 1974. 28 p., illus. $3.00.

No. 3. *Collections of Preserved Amphibians and Reptiles in the United States* compiled by David B. Wake (chair) and the Committee on Resources in Herpetology. 1975. 22 p. Out-of-print.

No. 4. *A Brief Outline of Suggested Treatments for Diseases of Captive Reptiles* by James B. Murphy. 1975. 13 p. $3.00.

No. 5. *Endangered and Threatened Amphibians and Reptiles in the United States* compiled by Ray E. Ashton, Jr. (chair) and the 1973–74 SSAR Regional Herpetological Societies Liaison Committee. 1976. 65 p. Out-of-print.

No. 6. *Longevity of Reptiles and Amphibians in North American Collections* by J. Kevin Bowler. 1977. 32 p. $3.00.

No. 7. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles* (1st ed.) by Joseph T. Collins, James E. Huheey, James L. Knight, and Hobart M. Smith. 1978. 36 p. $3.00. [see also numbers 12 and 19].

No. 8. *A Brief History of Herpetology in North America Before 1900* by Kraig Adler. 1979. 40 p., 24 photographs, 1 map. $3.00.

No. 9. *A Review of Marking Techniques for Amphibians and Reptiles* by John W. Ferner. 1979. 42 p., illus. $3.00.

No. 10. *Vernacular Names of South American Turtles* by Russell A. Mittermeier, Federico Medem and Anders G. J. Rhodin. 1980. 44 p. $3.00.

No. 11. *Recent Instances of Albinism in North American Amphibians and Reptiles* by Stanley Dyrkacz. 1981. 36 p. $3.00.

No. 12. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles* (2nd ed.) by Joseph T. Collins, Roger Conant, James E. Huheey, James L. Knight, Eric M. Rundquist, and Hobart M. Smith. 1982. 32 p. $3.00. [see also numbers 7 and 19].

No. 13. *Silver Anniversary Membership Directory*, including addresses of all SSAR members, addresses and publications of the herpetological societies of the world, and a brief history of the Society. 1983. 56 p., 4 photographs. $3.00.

No. 14. *Checklist of the Turtles of the World with English Common Names* by John Iverson. 1985. 14 p. $3.00.

No. 15. *Cannibalism in Reptiles: A World-Wide Review* by Joseph C. Mitchell. 1986. 37 p. $4.00.

No. 16. *Herpetological Collecting and Collections Management* by John E. Simmons. 1987. 72 p., 6 photographs. $6.00.

No. 17. *An Annotated List and Guide to the Amphibians and Reptiles of Monteverde, Costa Rica* by Marc P. Hayes, J. Alan Pounds, and Walter W. Timmerman. 1989. 70 p., 32 figures. $5.00.

No. 18. *Type Catalogues of Herpetological Collections: An Annotated List of Lists* by Charles R. Crumly. 1990. 50 p. $5.00.

No. 19. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles* (3rd ed.) compiled by Joseph T. Collins (coordinator for SSAR Common and Scientific Names List). 1990. 45 p. $5.00. [see also numbers 7 and 12].

No. 20. *Age Determination in Turtles* by George R. Zug. 1991. 32 p., 6 figures. $5.00.

PUBLICATIONS OF THE OHIO HERPETOLOGICAL SOCIETY

OHS was the predecessor to the Society for the Study of Amphibians and Reptiles. All publications international in scope. Paperbound as issued.

Volume 1 numbers 1–4, plus Special Publications 1–2 (all 1958), facsimile reprint, out-of-print.

Volume 2 (1959–1960), four numbers, $2.00 per number; numbers 3 and 4 out-of-print.

Volume 3 (1961–1962), four numbers, $1.00 per number; numbers 1 and 3 out-of-print.

Volume 4 (1963–1964), four numbers; double number 1–2, $4.00, numbers 3 and 4 $2.00 each.

Volume 5 (1965–1966), four numbers, $2.00 per number.

Special Publications 3–4 (1961–1962), $2.00 per number; number 3 out-of-print.

OTHER MATERIALS AVAILABLE FROM THE SOCIETY

The following color prints and brochures may be purchased from the Society. (*Extra postage required; see "Shipping and Handling Costs.")

HOLBROOK PORTRAIT. Full-color print (8¾ x 11¼ inches) of John Edwards Holbrook, father of North American herpetology, reproduced from the Daniel Huntington oil portrait of 1856–1857. Edition limited to 1000 copies. $6.00 each or $4.00 in quantities of 10 or more.

FIJI IGUANA PRINTS. Two full-color prints (7 x 10 inches) of *Brachylophus fasciatus* and *B. vitiensis*, as published in Journal of Herpetology, vol. 15, 1981. Special printing limited to 50 sets, individually signed by the artist, David M. Dennis. Set of two, $15.00.

*SILVER ANNIVERSARY COMMEMORATIVE PRINT. Full-color print (11½ x 15¼ inches) of a Gila Monster (*Heloderma suspectum*) on natural background, from a watercolor by David M. Dennis. Issued as part of Society's 25th Anniversary in 1982. Edition limited to 1000. $6.00 each or $5.00 in quantities of 10 or more.

*WORLD CONGRESS COMMEMORATIVE PRINT. Full-color print (11½ x 15 inches) of an Eastern Box Turtle (*Terrapene carolina*) in a natural setting, from a watercolor by David M. Dennis. Issued as part of SSAR's salute to the I World Congress of Herpetology, held at Canterbury, United Kingdom, in 1989. Edition limited to 1500. $6.00 each or $5.00 in quantities of 10 or more.

HERPETOLOGY AS A CAREER, by Henri C. Seibert, Ralph W. Axtell, Neil B. Ford, and Martin J. Rosenberg. 1985. 4 p. Brochure developed as an aid to students and counselors. Single copies free of charge; additional copies available for $0.25 each.

GUIDELINES FOR THE USE OF LIVE AMPHIBIANS AND REPTILES IN FIELD RESEARCH, by George R. Pisani, Stephen D. Busack, Herbert C. Dessauer, and Victor H. Hutchison, representing a joint committee of ASIH, HL, and SSAR. 1987. 16 p. Brochure covers animal care, regulations, collecting, restraint and handling, marking, housing and maintenance in field, and final disposition of specimens. $4.00 ($3.00 each in quantities of five or more copies).

SOCIETY MEMBERSHIP

Applications for SSAR membership may be obtained from Dr. Robert Aldridge (see "Society Publications") or from the SSAR treasurer, Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). ***HR*** especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Life History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints (8 x 10 inch preferred).

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc., 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Life History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles, Techniques Articles, Points of View, as well as news notes and other material, should be sent to the Editor.

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of three reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Life History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

RWH

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc. RFD 6 Box 1, Lawrence, Kansas 66046. *Herpetological Review* is composed using Microsoft Word and Aldus Pagemaker on Apple Macintosh computers. Camera-ready copy is produced on a Linotronic 230 Imagesetter at a resolution of 1700 dpi at Valley Type & Design, Fresno, California. All rights reserved. No part of this periodical may be reproduced without written permission of the editor.

SOCIETY FOR THE STUDY OF AMPHIBANS AND REPTILES

NEW PRICE for the

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The catalogue consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere.

COMPLETE SET: NUMBERS 1 - 505		$190.00
INDEX TO ACCOUNTS 1 - 400: Cross-referenced, 64 pages		$5.00
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$5.00
IMPRINTED POST BINDER: (note - two binders are needed for the 505 accounts)		$25.00
INCOMPLETE SET: NUMBERS	1 - 190	$60.00
	191 - 410	$70.00
	411 - 505	$60.00

Society For The Study Of Amphibians And Reptiles

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (4 issues annually), **Herpetological Review** (4 issues annually), and occasional issues of **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1991

Student member.....$25.00*	Sustaining member.....$50.00*
Regular member.....$35.00*	Contributing member.....$75.00*
Institutional subscription.....$60.00*	Life member (see below)..$600.00*

* **Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00 Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Life memberships may be paid in 3 consecutive payments. Subscriptions to **Herpetological Review** only are available for $12.00 annually. Subscriptions outside of the US require a surcharge of $8.00 for air delivery if airmail is desired. Subscribers to HR only are not members of the Society. Catalogue of American Amphibians and Reptiles: subscription is $15 annually ($3.00 air delivery surcharge if airmail is desired.). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

1992 ANNUAL MEETING
OF
THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

THE UNIVERSITY OF TEXAS AT EL PASO
EL PASO, TEXAS

2-6 AUGUST, 1992

Meeting Site

The University of Texas at El Paso (UTEP) is located in the Paso del Norte region of southwestern North America, at the junction of the states of Chihuahua, New Mexico, and Texas. El Paso is a major border city, its population of about 500,000 being augmented by that of Ciudad Juarez to a metropolitan area of 1.5 million people. The human population is considerably less dense for hundreds of kilometers in all directions from the two cities, forming an urban island in the otherwise xeric basin and range topography of the northern Chihuahuan Desert. The cultural milieu and biotic setting of the region thus offer an impressive range of entertainments. The meeting will be held about a month into the summer rainy season; warm to hot mornings, afternoon thundershowers, and balmy evenings can be generally expected.

Accommodations and Dining

The principal accommodations for the meeting will be at three downtown hotels: Travelodge Motor Hotel Central, Park Place Holiday Inn, and the Downtown Ramada Inn; these are located about 1.5 miles from the University campus. A shuttle bus will transport attendees every morning and evening to and from these hotels and the paper session locations. There are also several other hotels in the downtown areas, plus an assortment of motels within a short drive of the campus. A relatively small number of on-campus dormitory accommodations will also be available, perhaps for as many as 200 persons. Students are asked to reserve these dormitory spaces while they last (915-747-5352); comparatively wealthy faculty and other permanently employed persons are encouraged to make use of the off-campus accommodations.

On-campus eating facilities are limited during the intersession period, but arrangements have been made with the dormitory commons to serve meals to all meeting participants on a pay-as-you-go basis. Additionally, there are a few fast-food eateries, bar-restaurants, and restaurants on the eastern campus periphery within short to moderate walking distance of the Union.

Travel to El Paso

Overland travel to El Paso is facilitated by several roads, both paved and unpaved, leading into it. The city is served daily by several intercity bus lines: El Paso-Los Angeles Limousine Express, Greyhound Trailways Bus Lines, Texas, New Mexico, and Oklahoma Coaches, Inc., and Turismos Rapidos, S.A. Moreover, there is twice-a-week AMTRAK service here (info: 1-800-872-7245). The UTEP campus is located on the west side of the city, just north of downtown; on-campus parking is free and should not be a limiting resource. However, it is a good idea for attendees driving their personal vehicles to check their insurance provisions beforehand; like many border cities, we have many uninsured motorists.

El Paso has an international airport, located on the east side of the city and some eight miles from the campus. Shuttle transportation from the airport to the hotel will be provided by the hotels, and there are special rates for car rental (Avis) for UTEP conference attendees. Those participants coming from México should consider using the Ciudad Juarez airport and arranging for subsequent ground transportation across the border to El Paso.

Board and Business Meetings

The SSAR Board meeting will be held at 10AM on 2 August at the El Paso downtown Travelodge. The SSAR Business meeting is scheduled for after the lunch break on Thursday afternoon, 6 August, on the UTEP campus.

Traditional Events, Symposia, and Special Activities

The registration desk will open on Sunday, 2 August at noon at the Travelodge Hotel in downtown El Paso, and thereafter be moved to the UTEP campus for all day Monday and Tues-

HERP ART SHOW

AUG. 1 - OCT 3, 1992

The Centennial Museum at The University of Texas at El Paso

Wiggins and University, El Paso, Texas, 79968-0533 - 915-747-5565

All artists are invited to submit slides of paintings, drawings, photographs and sculpture of amphibians and reptiles for this juried show which will coincide with the 1992 annual meeting of The Society for the Study of Amphibians and Reptiles to be held at The University of Texas at El Paso, August 2-6, 1992. Best Painting, Best Drawing, Best Photograph and Best Sculpture awards of $200 each will be presented at the Opening Reception, August 3, 5-8 pm.

RULES:

1. Size of works must not exceed the following dimensions: Paintings (4 ft x 4 ft); Drawings (4 ft x 4 ft); Photography (4 ft x 4 ft); and Sulpture (Base 34 inches square x 6 feet in height, 300 pounds).

2. Two dimensional work must be framed ready for hanging with wire across back.

3. Below form must accompany slide of art work and must reach the Centennial by May 1, 1992. Please send slides of all sides of sculptures.

4. Shipping and insurance coverage costs to and from the Museum will be paid by the artist. An appropriate re-usable container must be used.

DATES:

May 1	Receipt of entry form and slides at the Centennial Museum for jurying.
June 1	Show selected and artists advised
July 1	Receipt of art work at the Centennial Museum
Aug. 1-Oct. 3	Exhibit: HERP ART
Aug. 3, 5-8 pm	Reception
Oct. 30	Works of art returned to artists

ENTRY FORM: Herp Art Show, Aug. 1- Oct 3, 1991
Mail to The Centennial Museum, UTEP, Wiggins and University, El Paso, TX 79968-0533

day. The paper and poster sessions, and symposia, will be held in the University Union Building (East), with some ancillary activities taking place in the Centennial Museum.

A plenary session with keynote speaker will open the meeting at 10AM on Monday, followed by a group photograph. The concurrent paper sessions, and the Chelonian Systematics symposium, will begin in the afternoon.

The first-day welcoming social will be held Monday, 3 August from 5-7PM in and on the grounds of the Centennial Museum, the University's museum of natural and cultural history. It will be followed by the Presidential Slide Show, in the University Union East.

The second day of the meeting will include contributed paper sessions, the continuation of the turtle symposium, the evening picnic dinner ("Fajita Fiesta"), and the traditional and infamous herpetological auction in the late evening. Tuesday will also begin the exhibit of live regional reptiles and amphibians (sponsored by the El Paso Herpetological Society and the Chihuahuan Desert Herpetological Society). This exhibit will gather together as many as possible of our 60+ species of local amphibians and reptiles.

Wednesday will be devoted to paper sessions, a continuation of the live exhibit, and a symposium on herp conservation in México. The near-traditional Dennis/Juterbock slide show will take place in the evening.

Thursday continues as the day before, with the addition of the Regional Societies conference. The SSAR Business Meeting scheduled for early afternoon and an (optional) trip to the Juarez race track for the evening. For Friday, a field trip to the Chihuahuan Desert Research Institute in Alpine will be available; this trip will include a BBQ cookout sponsored by the CDRI. Alternative Friday field trips consist of a hiking visit to Franklin Mountains Wilderness State Park, or an all-day visit to UTEP's Indio Mountains Research Station. Additionally, inexpensive "border-jumper" trolley excursions into Ciudad Juarez are available on a daily basis.

As an all-time first for SSAR, a juried herpetological art show will take place. Artists are encouraged to submit color slides of their work for this event; we hope to raise (very) modest monetary prizes for the winners in each of four categories. The show is being conducted under the auspices of the Centennial Museum, whose galleries have been reserved for this event during the meeting and an eight-week period afterward. Last year, the Museum had over 100,000 visitors; the serious artists among the membership will no doubt appreciate what this kind of public exposure can mean to them. For full explanation, see the entry form that appears elsewhere in this issue of *Herp. Review*. We are also contemplating a *Salon de Refusé* for artwork that a) either doesn't make it into the formal show in the Museum, or b) that attendees would like to bring with them for exhibition, but did not wish to enter into the formal show competition.

The 1992 meeting will also mark the debut of the Seibert Awards for outstanding student presentations. Provided by an anonymous donor and named in honor of lifetime SSAR supporter Henri Seibert, these cash awards will be presented for the best two orally-presented student papers ($250 for first prize, $150 for second). Entry requirements for the awards will be described in the forthcoming Call for Papers, but interested students are advised to begin working on their data, figures, and prose now.

Collecting Permits

Collection of reptiles and amphibians for scientific or educational purposes, or for recreational/private purposes in Texas and New Mexico is regulated by their respective state wildlife management authorities. Both these states require a permit for scientific collecting purposes, and a resident or non-resident hunting/fishing license for recreational take. Direct inquiries for scientific permits to: Resource Protection Branch, Texas Parks & Wildlife Department, 4200 Smith School Rd., Austin, Texas 78744, USA and/or New Mexico Department of Game and Fish, Villagra Building, Santa Fe, New Mexico 85703, USA.

Collection and/or export of herps in the sovereign nation of México for any reason is prohibited except by federal permit issued by the Dirección General de la Fauna y Flora Silvestre, an agency of the Secretaria de Desarrollo Urbano y Ecología (SEDUE). Illegally collected specimens may not be brought across the border into the United States without violating both Mexican and U.S. law.

Meeting Announcement

The 1992 annual meeting of the SSAR is being jointly sponsored by the El Paso Community College, the Sociedad Herpetología Mexicana, and the University of Texas at El Paso.

All interested persons, whether members of SSAR or not (and who are willing to pay the registration fee) are welcome to attend this meeting. The full meeting announcement, description of activities, call for papers and preregistration, and full information on accomodations will be mailed out to the SSAR membership no later than early March, 1992. For information in the interim, call Carl S. Lieb (915-747-5844) or Jerry Johnson (915-594-2214) during weekday business hours (Mountain Time). Overseas members will not automatically receive the meeting announcement, but may request a mailing either in writing or by calling one of the conference co-chairmen.

SSAR BUSINESS

SSAR ANNUAL MEETING REPORT: STATE COLLEGE 1991

Between 5 and 11 August 1991, State College, Pennsylvania was invaded by just over 500 herpetologists from the U.S. and overseas, as SSAR held its 34th annual meeting. The meeting, held jointly with the Herpetologists' League, was hosted by Pennsylvania State University; Linda Maxson, current SSAR president, chaired the local committee.

As a preliminary, President Maxson hosted a meeting of the Intersociety Liaison Committee at her house between 1600 and 1730 hours on 5 August 1991. This meeting was followed that evening by a dinner for SSAR and HL board members, editors, etc.; President Maxson was again the gracious and generous host.

The annual meeting of the SSAR Board of Directors was held on 6 August 1991, between 1000 and 1710 hours, in the Keller Conference Center on the Penn State campus; box lunches were available to minimize down time and allow informal business discussion to continue. Attending the board meeting were 11 of 12 board members, editors of three of the six publications, most committee chairs, and several members; reports were available for those publications and committees not represented.

A summary of business conducted was later presented at the Business Meeting (see below).

PRESENTATIONS

The meeting was officially called to order at 0900 hours on 7 August 1991 by President Maxson. Penn State President Joab Thomas (a member of the Biology faculty who referred to "his boss, Linda Maxson") welcomed us and recalled that HL President Gibbons was a student in the first Biology class he ever taught. Gibbons, in turn, introduced HL Distinguished Herpetologist Raymond B. Huey, who presented the lecture—Evolution of Performance: Reptiles and Amphibians as Models for General Biological Questions.

Distinguished Herpetologist Huey proffered both the theme that the evolution of performance is most effectively studied with animals that are well known demographically, and a plea for collaboration between those interested in functional biology and in demography. Huey noted that behavior, morphology, and physiology all affect performance, which affects genetic fitness. Approaches to the study of the evolution of performance include genetic historical patterns, functional bases, contemporary processes, and potential trajectories. Among several examples of interesting "performance questions" discussed, were: how does the performance (e.g., maximum speed or stamina) of an animal change as it ages; and, how does the performance of average animals change from year to year, or vary among populations?

Approximately 200 authors presented approximately 125 papers at 11 contributed paper sessions between 1300 hours 7 August 1991, and 1700 hours, 10 August 1991. There were also 37 poster presentations scheduled by 77 authors during two sessions. Two symposia, **Amphibian Declines and Habitat Acidification** and the **Conant Symposium,** involved another 92 authors and 58 presentations.

SOCIAL BEHAVIOR

Fortunately, as great as were the presentations and subsequent discussions among all of these scholarly sessions, we were well supplied with lighter fare by host Maxson, with able assistance from her local committee.

An opening mixer, with music by PSU Biology's Matt Bouchard, at the Nittany Lion Inn on 6 August 1991, welcomed a large crowd of annual meeters. It is doubtful that any appreciated the effort more than those who had spent the rest of the day in one of the two board meetings! We were again entertained and enlightened on the evening of 7 August 1991 by the annual multimedia presentations. **Herpetologists Past and Present** by Adler and Dennis, and **Amphibians of the Appalachians and Herpetology of the American West,** both by Dennis and Juterbock, played to an appreciative standing room crowd at Keller Auditorium. On 8 August 1991, we were all treated to a picnic at Beaver Stadium; entertainment was by PSU's Ben Ruth and the M & M's. Although the weather did not totally cooperate, it did not rain until the waning moments when we were all too sated to care. There was an unsubstantiated rumor that the post-prandial shower was planned by Linda to sober up the crowd before we got back to the dorms! The social pinnacle of this year's meeting, however, undoubtedly occurred at the auction, on 9 August 1991! Whereas auctioneer Collins performed his duties in his usual superb fashion, the spotlight that evening was really shining on the Ohio Herpetological Society Chorus. At least it was shining on those few members who were unable to hide from choral leader Kraig Adler. Best received was the debut of **The Ballad of Roger Conant.** Roger, of course, was also honored by a two-day symposium in recognition of his long and distinguished herpetological career; and, he was presented with a bound book of letters of recognition at a reception in his honor on 9 August 1991.

BUSINESS MEETING

President Maxson called the Annual Business Meeting to order at 1630 hours on Thursday, 8 August 1991 in the Keller Conference Center. She began by announcing the formation of a Grants in Herpetology endowment program. Maxson had previously solicited officers and former society presidents to become Founders of the endowment by contributing cash and/or special items for the annual auction (PSU football coach Joe Paterno donated an autographed football!). At the Board Meeting, earlier in the week, the SSAR Board budgeted a substantial contribution to this endowment.

Secretary Juterbock briefly summarized the annual meeting of the SSAR Board. He reported that the Board engaged in a substantial discussion of future meeting sites. SSAR voted to pursue an invitation from Craig Nelson to meet at Indiana University 10-14 August 1993. SSAR will soon produce a directory of the current (end of 1991) membership. SSAR will also pursue the possibility of publishing a directory of U.S. herpetologists (membership in any of the three major societies) plus North American Regional Societies and world herpetological societies with contact persons' names and addresses.

Publications Secretary Aldridge informed the board that he would need to be replaced, at least while he is on sabbatical. The committee to review the *Catalogue of American Amphibians and Reptiles* reported to the board that recent editor Villa had done a great job in getting the *Catalogue* published in a timely manner and converting the editorial process to desktop publishing. They also recommended, though noting that there is "no need to fix what isn't broken," that the *Catalogue* return to its original focus by completing accounts for North American taxa and that an editorial board be established.

Treasurer Taylor reported that the Society is in good financial shape with a stable membership base. All budgetary officials have been holding down costs and book sales have been good. The only dues categories with rates changing for 1992 are those for sustaining and contributing members. The board voted to close life memberships at the end of 1991.

Secretary Juterbock then presented a very brief summary of editorial and committee business that had transpired at the board meeting. Bob Hansen was introduced as the new editor of *Herpetological Review.* Both the *Journal of Herpetology* and *Herpetological Review* now enjoy minimal lag time between acceptance of articles by the editors and their subsequent appearance in print. The Conservation Committee reported that they are investigating the possibility of producing a "Monetary Values of Reptiles" report paralleling the one produced for amphibians. The Grants in Herpetology were announced (see *Herp. Review* 22:76). The Kennedy Student Award was announced (elsewhere in this issue). Both the Regional Society and Zoo Liaison Committees are working on symposia/paper sessions for the El Paso meeting.

Bob Webb reported for the 1992 Local Committee on plans for the El Paso meeting, 2-6 August 1992. The meeting will be cohosted by the University of Texas at El Paso (where we will meet in the student union) and El Paso Community College; it will be cosponsored by the Sociedad Herpetologia Mexicana. Descriptions of the meeting site and plans have been, and will continue to be, found in issues of *Herp. Review.* The meeting should be a great one!

Meg Stewart, Chair of the Nominating Committee, announced the candidates for terms of office beginning in 1992. President-elect: Thomas H. Fritts and Stephen G. Tilley; Secretary: J. Eric Juterbock; Treasurer: Douglas H. Taylor; Director: Robin Andrews and Stephen A. Perrill; and, Director (Zoos): Peter Tolson and Bern Tryon. There being no further nominations from the floor, Mushinsky moved (Christiansen seconded) to close the nominations; the motion passed unanimously.

A long series of resolutions (see below) were unanimously accepted by the gathering. President Maxson then announced that the picnic was ready to begin.

Finally, President Maxson presented the official SSAR Presidential Gavel to President-elect Moll, who adjourned the meeting at 1730 hours.

Respectfully submitted,

J. ERIC JUTERBOCK
SSAR Secretary ●

RESOLUTIONS

San Diego Natural History Museum (Joint)

Whereas the San Diego Natural History Museum has, over its distinguished 119-year history, become one of the nation's major repositories of knowledge and representative flora and fauna of the Southwest; and,

Whereas the San Diego Natural History Museum's extensive and high-quality collections of plants and animals (notable among which is the Laurence M. Klauber herpetological collection) are major resources for the study of regions far beyond San Diego County; and,

Whereas these holdings represent thousands of hours of collection, identification, and cataloguing, which at current wages would require millions of dollars to duplicate; and,

Whereas the growing population and industrial pressures on the Southwest mean that the Museum's collections, and the research and public education that San Diego Natural History Museum scientists are in a unique position to perform will become increasingly more important in the future to scientists, to environmental policy makers and those charged with implementing such policy, to urban planners, to agricultural interests, and to the general public;

Therefore, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles (SSAR) and the Herpetologists' League (HL), professional scientific societies devoted to the study of amphibians and reptiles, emphatically reaffirm to the San Diego Natural History Museum Board of Trustees and to corporate and civic leaders in San Diego County the importance of the extensive systematics collections of the Museum, representing a tremendous, and for many habitats irreplaceable, chronological database of the changing biota of California, the Southwest, and of tropical habitats; and, be it further

RESOLVED that these Societies similarly reaffirm the importance of adequate professional staff to assure the maintenance, strengthening and timely utilization of these collections; and, be it further

RESOLVED that these Societies do indeed recognize and appreciate the financial obstacles faced by the Board of Trustees in finding adequate funding to assure the ongoing excellence of the Museum; and finally, be it

RESOLVED that these Societies will communicate with those in other disciplines to seek unanimous scientific support for the Board of Trustees in its effort to sustain and enhance the Museum.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles and the Herpetologists' League, August 8, 1991 at their joint Annual Meeting.

Honoring Outgoing SSAR Officers

Whereas the following individuals have given freely of their time, skills, insight, and knowledge to the Society for the Study of Amphibians and Reptiles in this past year, thereby advancing its goals and furthering its growth and development as an international society; and,

Whereas these persons have, in the finest tradition of the Society, passed on to their institutions as much of the associated costs of this service to SSAR as was possible; and,

Whereas said Society is greatly indebted to these persons for their continual efforts in its behalf; and,

Whereas the Society urges these persons not to ride off into the sunset, but rather to, with or without official titles, continue to be available as resources to help those who follow better guide SSAR;

Therefore, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles offers its most sincere thanks to the following persons who have served in these capacities:

ROBERT D. ALDRIDGE— Herpetological Translations Coordinator
DONAL BOYER— Chair, Zoo Liaison Committee
WILLIAM S. BROWN— President
HAROLD DUNDEE— Chair of the 1990 Local Committee
CARL GANS— Chair, Nominating Committee
ERNEST A. LINER— Director
MARTIN J. ROSENBERG— Director
HENRI SEIBERT— Immediate Past-President
JOHN SIMMONS— Managing Editor, *Herpetological Review*

Adopted by the Society for the Study of Amphibians and Reptiles August 8, 1991 at its Annual Business Meeting.

Honoring Outgoing SSAR Editors

Whereas 1990-1991 was a period of significant restructuring and change in the way two of the Society's publications are composed; and,

Whereas the bumpy but successful transition to in-house computer composition of these publications has allowed far more efficient utilization of SSAR's publications budget, thereby providing members with far more information than was previously financially possible; and,

Whereas the editors of these publications have stepped down to pursue other professional activities they have long neglected during their extensive time commitment to the Society; and,

Whereas this same period also marked the end of Jim Vial's long and distinguished career as Managing Editor of the *Journal of Herpetology* so that he too might pursue long-neglected things; and,

Whereas these persons have made notable constructive impacts on the publications they served so well and upon the Society in general;

Therefore, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles offers its most sincere appreciation to:

MARTIN J. ROSENBERG— Editor, *Herpetological Review*
JAMES L. VIAL— Managing Editor, *Journal of Herpetology*
JAIME VILLA— Editor, *Catalogue of American Amphibians and Reptiles;*
and be it further

RESOLVED that the Society wishes these persons the very best success in their endeavors.

Adopted by the Society for the Study of Amphibians and Reptiles August 8, 1991 at its Annual Business Meeting.

Clemmys Conservation (Joint)

Whereas natural populations of the wood turtle, the spotted turtle, the western pond turtle, and the bog turtle *(Clemmys insculpta, Clemmys guttata, Clemmys marmorata,* and *Clemmys muhlenbergii)* are adversely affected by the loss and degradation of their habitats, and are heavily exploited by the commercial pet trade; and,

Whereas the above mentioned species are, by the nature of their habits and population structure, highly vulnerable to the effects of mass collection; and,

Whereas the above mentioned species reportedly are declining in numbers and already are legally protected from commercial exploitation in most states and provinces in which they occur;

Therefore, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles (SSAR) and the Herpetologists' League (HL), professional scientific societies devoted to the study of amphibians and reptiles, respectfully urge all states and provinces that have populations of the above mentioned species to increase efforts to protect their natural habitats and to move quickly to prohibit their commercial collection, as well as to limit and regulate private and scientific collection of these species; and, be it further

RESOLVED that the SSAR and HL urge the United States Fish and Wildlife Service and the Canadian Wildlife Service to initiate a review of these species and to coordinate enforcement efforts with the states and provinces, with the purpose of preserving existing populations of these species; and, be it further

RESOLVED that copies of this resolution be forwarded to the directors of the above mentioned agencies, and to wildlife agencies of all states and provinces in which turtles of the genus *Clemmys* occur.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles and the Herpetologists' League, August 8, 1991 at their joint Annual Meeting.

Thanking The Local Committee (Joint)

Whereas over 500 herpetologists invaded the peaceful (except for deer season) woodlands of Pennsylvania; and,

Whereas Local Committee Chair Linda Maxson, ably assisted by Carla Hass, Blair Hedges, Thomas Lopez, Tammi Jo Cox, Marlene Adams, Peter Petokas, Noel Smith, Joane Stoneberg, Matt Bouchard, Ben Ruth, Joan Walsh, Jack Sinclair and the Conference Center Staff, and many others, performed a great service for the SSAR and the Herpetologists' League by agreeing to undertake the arduous task of hosting a meeting of this size; and,

Whereas the Local Committee has no doubt learned the true significance of volunteering to do so and shall never do so again; and,

Whereas the ageing and/or more conservative nature of the present membership of these esteemed societies has, believe us Linda, made their task less arduous than it might have been 15 years ago; and,

Whereas this meeting maintains a tradition whereby the joint SSAR and HL annual meeting provides an outstanding forum for the dissemination of ideas and information;

Therefore, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles and the Herpetologists' League offer their most sincere thanks to these persons who worked so hard to make this meeting a success.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles and the Herpetologists' League, August 8, 1991 at their joint Annual Meeting. ●

KENNEDY STUDENT AWARD

The Kennedy Award Committee has completed its work for volume 24 of the *Journal of Herpetology*. The Committee has selected "Ecology and behavior of the Gila monster in southwestern Utah" by Daniel D. Beck. The paper is credited to the Department of Biology and Ecology Center, Utah State University and was part of Daniel's M.Sc. thesis. Daniel is currently at the Department of Ecology and Evolutionary Biology at the University of Arizona, Tucson. ●

THANKS TO REVIEWERS

The (past) editor would like to acknowledge the following individuals who reviewed manuscripts for *HR* during the past several years. Their service to the Society is greatly appreciated.

R. Anderson, W. Auffenberg, W. Bakhurst, S. Barnard, J. Behler, J. Berry, P. Brazaitis, D. Breininger, W. Brown, J. Burger, G. Burghardt, R. Burke, R. B. Bury, C. Carpenter, D. Chiszar, D. R. Clark, J. T. Collins, S. Corn, D. Crews, G. Dalrymple, B. Demeter, H. Dessauer, J. Dixon, C. K. Dodd, G. L. Dryden, H. Dundee, D. Duvall, H. Ellerbrock, Z. Ermi, G. Fellers, J. Ferner, L. Fitzgerald, L. Fleishman, D. Forester, R. Franz, F. L. Frye, A. Georges, P. Gregory, G. C. Grigg, J. Groves, G. Hammerson, M. Hayes, L. Hayes-Odum, J. Hendrickson, T. Henwood, J. M. Hero, R. Heyer, D. Hillis, G. Hoff, W. Horn, R. E. Honegger T. Hoshiko, L. Houck, R. Huey, G. R. Hughes, R. Inger, J. Iverson, D. Jackson, E. Jacobson, F. W. King, R. Klingenberg A. Kluge, J. Kushlan, J. Lazell, J. Legler, A. Lewis, L. Licht, M. Little, M. J. Littlejohn, R. Lohoefener, J. Losos, P. Maderson, R. Marquez, T. Matson, L. Maxson, F. Mazzotti, R. McDiarmid, B. Means, A. Meylen, S. Minton, J. Mitchell, P. Moler, D. Moll, S. Moody, P. Morin, J. Mortimer, J. B. Murphy, H. Mushinsky, R. Opferman, L. Orr, J. Pachmann, M. Packard, J. Palis, M. Paulissen, R. Pawley, R. Pfingsten, E. Wells, D. Werner, R. Wilkinson, L. D. Wilson, J. Wright, E. Zalisko, G. Zug, R. Zweifel. ●

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The Board of the Society for the Study of Amphibians and Reptiles and the editors of the *Catalogue of American Amphibians and Reptiles* wish to acknowledge and thank the following persons for reviewing *Catalogue* accounts:

Charles C. Cole, Ronald I. Crombie, Dave Darda, Robert W. Henderson, David M. Hillis, John B. Iverson, Julian C. Lee, Jeffrey E. Lovich, James R. McCranie, Roy W. McDiarmid, Don Moll, Gregory K. Pregill, Charles A. Ross, Albert Schwartz, Michael E. Seidel, John B. Thorbjarnarson, Jaime D. Villa, David B. Wake, Joseph P. Ward, George R. Zug.

Accounts on a number of American taxa and many U.S. forms remain unassigned. If you are interested in writing an account, please contact the pertinent section editor: **Marvalee H. Wake** (Gymnophiona), Department of Integrative Biology, University of California, Berkeley, California 94720, USA; **R. Wayne Van Devender** (Caudata), Department of Biology, Appalachian State University, Boone, North Carolina 28608, USA; **John D. Lynch** (Anura), School of Life Sciences, University of Nebraska, Lincoln, Nebraska 68508, USA; **Michael W. Klemens** (Testudines), American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024-5192, USA; **Andrew H. Price** (Sauria and Amphisbaenia), Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas 78744, USA; **Larry David Wilson** (Serpentes), Department of Biology, Miami-Dade Community College, South Campus, 11011 S.W. 104th Street, Miami, Florida 33176, USA; **I. Lehr Brisbin** (Crocodylia), Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29801, USA. ●

CHELONIAN SYSTEMATICS, EVOLUTION, AND ZOOGEOGRAPHY SYMPOSIUM ANNOUNCEMENT

A symposium on the above subjects will be held in conjunction with the SSAR Meeting in El Paso, Texas (2-6 August 1992). Topics to be presented concern molecular, phylogenetic, and traditional investigations of chelonian relationships and distribution. To date, the following researchers are *tentative* presenters for the program: John Bickham, Brian Bowen, John Carr, Brian Hanks, Eugene Gaffney, John Iverson, John Legler, Trip Lamb, Peter Meylan, Pat Minx, Edward O. Moll, Anders Rhodin, and Roger Wood.

The program is open for additional participants. Others wishing to present a paper in the program are invited to submit a title and brief summary of their topic by January 15, 1992. Final selection of participants will be made by January 30. Those interested in being presenters should contact either of the following:

Edward O. Moll
Department of Zoology
Eastern Illinois University
Charleston, Illinois 61920, USA
Phone: (217) 581-5410
FAX: (217) 581-2722

John Carr
Conservation International
1015 18th St. N.W.
Suite 1000
Washington, D.C. 20036, USA
Phone: (202) 429-5660.

NEWSNOTES

REQUEST FOR PHOTOS AND REFERENCES OF GARTER SNAKES

The University of Oklahoma Press has contracted to publish "The Garter Snakes: Systematics and Life History" by D. A. Rossman, N. B. Ford, and R. A. Seigel. The authors wish to show examples of every subspecies of all species of this genus. Anyone willing to loan quality color slides of rarer subspecies for use in this publication should send a list of available photos to Douglas A. Rossman, Museum of Zoology, Louisiana State University, Baton Rouge, Louisiana 70803, USA. Any slides used will receive proper acknowledgment in the book.

In addition, the authors wish to make the references as complete as possible. Any researchers with papers in press or who have access to unpublished Master's theses or status reports are encouraged to send reprints, manuscripts, or citations to any of the above authors. Papers should be sent no later than January, 1993. ●

PLETHODONTID SUMMER COURSE

The Biology of Plethodontid Salamanders will be offered 4–27 June 1992 at the Highlands Biological Sta-

tion in North Carolina. The instructor will be Stephen G. Tilley. The southern Appalachian region is renowned for the diversity of its salamander fauna. This course is designed to acquaint students with plethodontid salamanders and to show how studies of these animals have enhanced our understanding of a series of major evolutionary and ecological topics. Each of these topics will occupy one week of the course and will be treated by lectures, field and laboratory exercises, and discussions of original research papers. Numerous field trips to significant salamander localities are a highlight of the course. Advanced undergraduate or graduate credit is available through either The University of North Carolina at Chapel Hill or Western Carolina University. For information, contact:

Dr. Richard Bruce
Highlands Biological Station
P.O. Box 580
Highlands, North Carolina 28741, USA.

●

ZOO RESEARCH GRANTS

The American Association of Zoo Keepers announces the availability of two $750 research grants in the field of zoo biology. Interested applicants should direct their inquiries to Sue Barnard, Chairperson, AAZK Research/Grants Committee, Zoo Atlanta, Department of Herpetology, 800 Cherokee Ave., SE, Atlanta, Georgia 30315, USA. ●

SOUTHWESTERN RESEARCH STATION STUDENT RESEARCH GRANTS

The American Museum of Natural History awards several grants each year of approximately $400-$800 to graduate students or post-doctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona. Information and application forms concerning this program and other Museum programs can be obtained by writing:

Office of Grants and Fellowships
American Museum of Natural History
Central Park West at 79th Street
New York, New York 10024-5192, USA.

Application due date is 15 February 1992. Address questions concerning the Research Station to:

Dr. Wade C. Sherbrooke, Director
Southwestern Research Station
Portal, Arizona 85632, USA
(602) 558-2396.

●

SWRS VOLUNTEER OPPORTUNITIES

Approximately 20 volunteer positions are open in 1992 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for four hours per day of routine chores, with the remaining time available for research activities.

The program is open to both undergraduates and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 15 and November. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March through May) should submit forms by 15 February, summer volunteers (June – August) by 1 April, and fall volunteers (September – November) may apply any time.

For application forms, contact:

Dr. Wade C. Sherbrooke, Director
Southwestern Research Station
Portal, Arizona 85632, USA
(602) 558-2396.

●

HERPETOLOGY ON-LINE COMPUTER NETWORK

The Herpetology Online Computer Network (Herp-Net) invites all SSAR members to participate in its international communication system for those interested in the study or conservation of reptiles and amphibians. Herp-Net was created to facilitate the exchange of information and ideas among zoos, herpetologists, veterinarians, biologists, conservationists, and the interested public. Discussions include husbandry, field biology, medical aspects, captive requirements, reproduction, etc. Herp-Net is available 24 hours/day via ANY modem-equipped computer or terminal. The direct dial system has 10 incoming phone lines connected to **215-464-3563.**

Herp-Net currently contains the following sections:

A public message area that works like an electronic bulletin board. Questions may be posted for other callers to see and discussions and informal conversations take place here. New topics are created daily and range from field reports, to genetics, to UV lighting, to photography, to zoogeography, to student research requests, to specific captive requirements for a species, and so on.

A file archive area is available to transfer articles, programs, data, book reviews, and even electronic images to or from your computer. Thousands of pages of information are available. Book reviews are periodically added as new titles are received.

Several online databases for members' interests, regional societies, and veterinarians may be searched.

A free book search service for out-of-print to rare titles in zoology or natural history (requests may also be mailed).

A listing of "herp crimes"—thefts of animals, educational materials, specimens, and so forth.

A calendar of international meetings, conferences, and other events relating to reptiles/amphibians is constantly being compiled and updated. This list may be read on-line or downloaded to your printer.

New projects are added as interest dictates. Many organizations have a representative on-line with us and callers benefit from the experience of others with similar interests.

The Herp-Net project is supported by private contributions and an all-volunteer staff. For more information contact:

Mark F. Miller
System Administrator
Herp-Net
P.O.Box 52261
Philadelphia, Pennsylvania 19115,
USA

Voice or FAX messages are accepted on **215-464-3561** anytime. ●

INFORMATION REQUEST

All collections, public or private, holding living specimens of the black pine snake, *Pituophis melanoleucus lodingi* or Louisiana pine snake, *Pituophis melanoleucus ruthveni*, or collections having held these snakes in the past are encouraged to participate in the formation of the AAZPA North American Regional Studbook for these taxa, which is currently in preparation. Both reptiles may be threatened in the wild, and the studbook will aid in the genetic management of the captive population.

If you would like to contribute data and be included in the project please contact:

Steve Reichling
Memphis Zoo and Aquarium
2000 Galloway Ave.
Memphis, Tennessee 38112, USA
(901) 726-4787.

ANNOUNCING A SYSTEMATICS PRIORITIES INITIATIVE

The American Society of Plant Taxonomists, the Society of Systematic Biologists, and the Willi Hennig Society have formed a steering committee to organize an initiative to document research trends and priorities within systematics, to be called SYSTEMATICS AGENDA 2000: INTEGRATING BIOLOGICAL DIVERSITY AND SOCIETAL NEEDS. SYSTEMATICS AGENDA 2000 will have as its major themes the role of systematics in the analysis of biodiversity, the integrative role of systematics in comparative biology, and the importance of systematics in human affairs. The initiative is charged with (1) identifying important research trends and questions and with establishing priorities among them, (2) assessing the status of current infrastructures supporting systematics research and evaluating future needs, (3) documenting the broad role that systematics plays in human affairs and evaluating its future contributions and needs in those endeavors. SYSTEMATICS AGENDA 2000 has established 28 committees to undertake this initiative.

A detailed description of SYSTEMATICS AGENDA 2000. including a list of the members of the Steering Committee and the co-chairs of all Standing Committees, can be found in the last issue (no. 4, 1991) of *Cladistics*, *Systematic Botany*, and *Systematic Zoology*. All systematists, and nonsystematists interested in the role that systematics plays in their discipline, are invited to contact the appropriate committee co-chairs to discuss how each might contribute to this effort. ●

MEETINGS

HIGHLANDS CONFERENCE ON PLETHODONTID SALAMANDERS

The Highlands Conference on Plethodontid Salamanders will be held from 31 May – 2 June 1992 in Highlands, North Carolina. This Conference is the third sponsored by the Highlands Biological Station, and will follow the tradition of the First (1972) and Second (1982) Conferences in exploring new directions in plethodontid research. The Conference features two contributed poster sessions, invited papers, and a symposium. All interested are welcome to attend; those who work on plethodontid salamanders are encouraged to participate.

The symposium, Recent Advances in Plethodontid Research, will focus on the following topics:

Life History Ecology
Social Behavior
The Nervous System of Plethodontid Salamanders
Development and Evolution
Molecular Approaches
Geographic Variation and Speciation
Phylogenetic Issues

To receive the Call for Papers or registration material, contact:

Dr. Robert Jaeger
Department of Biology
University of Southwestern Louisiana
Lafayette, Louisiana 70504-2451,

●

INTERNATIONAL SYMPOSIUM— "BIODIVERSITY IN MANAGED LANDSCAPES: THEORY AND PRACTICE"

The symposium will be held at the Capitol Plaza Holiday Inn, Sacramento, California, 13-17 July 1992. This milestone symposium will be coordinated with The Biodiversity Conservation Strategy Programme organized by the International Union for the Conservation of Nature and Natural Resources (IUCN), the United Nations Environment Programme (UNEP), and the World Resources Institute (WRI), and is initially being co-sponsored by a variety of U.S. Agencies and environmental groups including the Forest Service, Fish and Wildlife Service, National Park Service, Bureau of Land Management, Environmental Protection Agency, Smithsonian Institution, Ecological Society of America, The Nature Conservancy, Wilderness Society, and The Wildlife Society. The program's objectives will be to provide the scientific basis for understanding biodiversity, document case examples of theory and concepts applied at differing scales, and examine policies that affect its conservation. The result

will be the publication of a reference text for managers, scientists, and students that focuses on actual accomplishments and strategies for conserving biodiversity. A distinguished group of invited speakers will address: genetic diversity; species diversity; community diversity; landscape diversity; setting objectives and priorities, inventory, monitoring, and assessment; management strategies; and policy and social considerations. For further information write to:

Dr. Robert C. Szaro

FAX (202) 205-1551

LEGISLATIVE ALERT/ CONSERVATION

The following final and/or proposed listings, regulations, and general information have been announced by governmental regulatory agencies. Pertinent Federal Register (FR) citations are given for U.S. notices.

U.S.A.: *Thamnophis gigas* (giant garter snake); On September 21, 1990, the USFWS received a petition from the President of the California-Nevada Chapter of the American Fisheries Society to list the giant garter snake as an endangered species. This species has been classified by the Service as a category 2 candidate species since 1985 (FR Vol. 50:37958). The giant garter snake historically occurred from the Buena Vista Lake Basin near Bakersfield, Kern Co., California north to Chico, Butte Co. The petition stated that the snake has experienced significant losses of habitat and populations, and a reduction in its range. This is attributed to a 98% loss of wetland and riparian habitats within the range. The USFWS is soliciting additional data, comments, and suggestions concerning the status of this species.

U.S.A., Michigan: *Nerodia erythrogaster neglecta* (northern copperbelly watersnake); The Michigan Nature Association, 7981 Beard Road, P.O. Box 102, Avoca, Michigan 48006 (313) 324-2626 is launching a fund-raising drive to purchase land deemed critical to the survival of the largest and healthiest population in the post-glacial range of the northern copperbelly watersnake. Potential threats to the site include a proposal to re-open a currently closed road that traverses the snake's swamp-forest habitat. Further information can be obtained by writing the Michigan Nature Association.

FEATURES

RATTLESNAKES AND MEXICAN FOLK MEDICINE

Dried rattlesnake flesh and powdered rattlesnake bones (polvo de cascabel) are widely used folk medicines in parts of México. In rural sections of the state of Querétaro, they are considered to be a virtual panacea and are used particularly for skin and kidney diseases and for prevention and treatment of cancer. They are occasionally used by upper class urban Mexicans and North Americans residing in México. A survey of Hispanic patients in El Paso, Texas hospitals showed that about a third had used rattlesnake remedies themselves or their relatives had used them (Bhatt et al. 1988).

Vendors of fruits, candies, handicrafts, and other articles are ubiquitous along Mexican highways. For many years the Indians near Entronque Huizache (intersection of Mexican Federal highways 57 and 80) in semiarid northern San Luis Potosí have sold various animals to motorists. Until about 1986 these were mostly ground squirrels and other small mammals and birds such as hawks and parrots. However, on our 1987, 1988, 1989, and 1991 trips, we noted dried snake carcasses prominently displayed. Most were of animals about 70 to 100 cm long, but a few were considerably larger. They were stretched on crude wooden frames (Fig. 1). During our two trips in 1991, we estimated there were 20 frames over a distance of about 2 km and each held 8 to 14 carcasses. In 1987 particularly, we believe the number of frames was larger, perhaps as many as 30. An estimated 100 to 200 snakes were on display on each of our visits.

On the frames we have examined closely, most of the carcasses were clearly those of rattlesnakes (*Crotalus* sp.), but some seemed too slender and probably were colubrids such as *Pituophis*. Some of these had two or three rattles obviously sewed to the tail. We presume the Indians obtain these snakes locally. We have no idea of the daily or weekly sales volume or of the "shelf life" of a carcass, but this curious enterprise may significantly deplete local populations of rattlesnakes and other large to medium-sized species.

Use of these rattlesnake remedies has its dangers, the most significant being infection with salmonella bacteria which commonly infect snakes and have been isolated from rattlesnake capsules and a dried carcass (Babu et al. 1990). About two dozen cases of generalized *Salmonella arizona* infections have been reported from the Los Angeles, California area. Nearly all those infected gave a history of having taken capsules of powdered rattlesnake flesh for serious underlying conditions. There were six deaths, three in patients with AIDS (Riley et al. 1988; Waterman et al. 1990). Similar cases have been reported in other cities near the Mexican border.

We thank Brooks Minton de Cervantes for information regarding use of rattlesnake remedies in Querétaro.

DISTRIBUTIONAL NOTES ON *Nerodia harteri harteri* IN PARKER AND PALO PINTO COUNTIES, TEXAS

The Brazos water snake, *Nerodia harteri harteri*, has a limited distribution, and knowledge of its ecology and occurrence within its range has accumulated slowly since its description (Trapido 1941). Literature specific to *N. h. harteri* is limited to several brief distributional reports (Mecham 1983; Smith 1983; Wade 1968). Scott et al. (1989) recently reviewed the status of *N. harteri* populations. Because of its limited distribution and specific habitat requirements, *N. harteri* has been the focal issue in controversial river development projects. *Nerodia h. harteri* is currently listed as Threatened by the Texas Parks and Wildlife Department.

Scott et al. (1989) reported a 100 km hiatus in the present distribution of *N. h. harteri* along the Brazos River. This hiatus encompasses a river section from Hittson Bend (Palo Pinto Co.) downstream to Lake Granbury (Hood Co.). Littlefield Bend lies primarily in the southwestern corner of Parker County, just east of the Palo Pinto/Parker County line and approximately in the center of the hiatus (Fig. 1). Scott et al. (1989) report six areas of suitable habitat within the hiatus where *N. h. harteri* were not found, including two in the Littlefield Bend area. They also report two historical records from Palo Pinto County within the hiatus. Here we document the continued occurrence of *N. h. harteri* within the hiatus and report new records from the Littlefield Bend area of Parker County. This constitutes a new county record for Parker County, Texas (Dixon 1987; Scott et al. 1989). All specimens were deposited in the University of Texas at Arlington Collection of Vertebrates (UTACV). The following represents the new distributional information for *N. harteri harteri* in Palo Pinto and Parker Counties, Texas (Fig.1).

A. Texas: Palo Pinto Co.: 9.6 km northeast of Palo Pinto on the Brazos River (Moffitt Bend). 28 July 1961. UTACV R-597. Previously unreported historical record.

B. Texas: Palo Pinto Co.: 100 m SE of U.S. Highway 281 bridge over Brazos River at mouth of Coffee Creek. 30 April 1988. Three juveniles observed by MED under flat rocks on south bank; cloudy; temperature ca. 19°C. Rediscovery of species at an historical locality (Scott et al. 1989).

C. Texas: Parker Co.: 3.8 air km NW of Interstate Highway 20 bridge over Brazos River. 1 June 1986. Adult observed by MED on rocky, east bank next to deep, slowly moving water. New locality record.

D. Texas: Parker Co.: 4.6 air km NNW of Interstate Highway 20 bridge over Brazos River. 1 April 1989. Three juveniles collected (UTACV R-27183-27185) under flat rocks on north gravel bank. One adult female collected (UTACV R-27186) ca. 100 m downstream on south bank at the edge of water ca. 1 meter deep, while trying to eat a juvenile channel catfish, *Ictalurus punctatus* (130 mm TL). New locality record.

E. Texas: Parker Co.: ca. 2.4 km N of Interstate Highway 20 bridge over Brazos River. 16 September 1989. UTACV R-27187. One adult female collected while basking on a limb overhanging swiftly moving water ca. 1.5 m deep. The river bank consisted of large boulders and trees; no riffles within 3 km up or downstream. New locality record.

The following areas of suitable "juvenile *N. harteri* habitat" (Scott et al. 1989) were also located in the Littlefield Bend region. Although no *N. harteri* were found at these sites, juvenile *N. erythrogaster* and *N. rhombifera* were found here under flat rocks.

F. Texas: Palo Pinto Co.: 3.2 air km NE of U.S. Highway 281 bridge over Brazos River.

G. Texas: Parker Co.: 5.3 air km NNW of Interstate Highway 20 bridge over Brazos River. The discovery of these *N. h. harteri* from Littlefield Bend indicates that present day populations are not as widely separated along the Brazos River as previously thought (Scott et al. 1989).

ACKNOWLEDGMENTS

We thank M. Harvey, K. Kittelson, and T. Dorcas for assistance in the field. J. A. Campbell provided helpful comments on the manuscript and logistical assistance. J. L. Darling curated the specimens expeditiously. This work was authorized by the Texas Parks and Wildlife Dept. (permit number: SPR-0590-072).

PREDATION ON AVIAN EGGS BY THE BOID SNAKE, *Eunectes notaeus*

Besides the well-known, specialized egg-eater *Dasypeltis* (Gans 1974), several colubrid snakes (including *Boiga, Conophis, Elachistodon, Elaphe, Lampropeltis, Pseustes,* and *Spilotes*) include bird eggs in their diets (Cunha and Nascimento 1978, Greene 1989, Mushinsky 1987, Savitzky 1983, Scott 1983). To date, documented observations on avian egg-eating seem restricted to colubrid snakes.

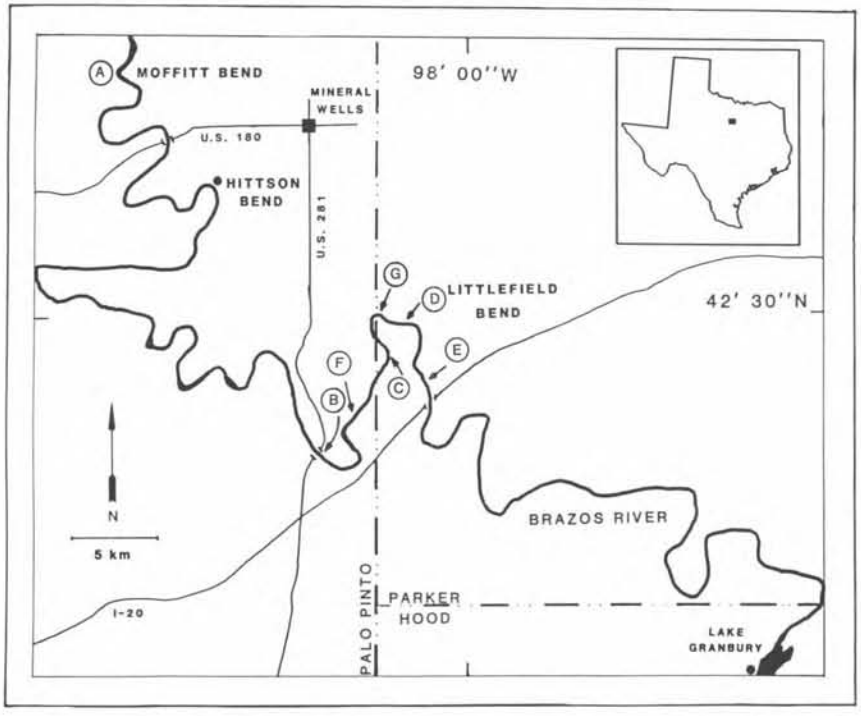

Figure 1. The 100 km hiatus in the distribution of *Nerodia h. harteri* along the Brazos River reported by Scott et al. (1989). Closed circles represent localities where snakes were found by Scott et al. (1989). Lettered localities are referred to in text.

Constricting anacondas, boid genus *Eunectes*, are known to mainly feed on avian and mammalian prey (Cunha and Nascimento 1978, Ditmars 1912, Wehekind 1955), and occasionally on crocodilians and turtles (Parker and Grandison 1977, Yamashita et al. 1985). In southwestern Brasil we observed the yellow anaconda, *E. notaeus*, feeding on prey as diverse as fishes, turtles, caimans, wading birds, and rodents; this snake even scavenges, a habit anticipated by Sazima and Strüssmann (1990). Here we report on an observation of avian egg-eating by *E. notaeus*.

Field work was done in the Pantanal wetlands at Poconé, Mato Grosso, southwestern Brasil. The Pantanal covers ca. 100,000 km^2 of almost flat, seasonally flooded terrain (additional information in Prance and Schaller 1982). As part of a study on the Pantanal herpetofauna, 33 anacondas were caught and palpated to determine whether their stomach contained food. Whenever a bolus was detected, the snake was forced to regurgitate its prey (Slip and Shine 1988), which was then examined.

A juvenile *E. notaeus* (165 cm SVL, 3.2 kg) was found on 11 July 1990, apparently basking on an emergent mat of aquatic vegetation at 1745 h, with an air temperature of 19.5°C. Upon manipulation the snake regurgitated two intact bird eggs; an additional egg was broken during palpation. The eggs were identified as those of limpkin (Harrison 1978), *Aramus guarauna*, a common wading bird in the Pantanal.

Head length and head width of the snake were 5.4 cm and 3.3 cm, respectively. The two intact eggs measured 6.2 x 4.3 cm and ca. 6.0 x 4.5 cm, and weighed about 60 g each, a prey/predator mass ratio (Pough and Groves 1983) of ca. 0.02. This is a very low mass food item for a boid snake (average of 0.36; see Greene 1983).

The eggs were all swallowed by their pointed end first, an orientation commonly found in other instances of egg-eating by snakes (see Gans 1974). Egg handling by *E. notaeus* may possibly be similar to that employed by the boid *Loxocemus bicolor* when feeding on reptile eggs—either pushing the egg against the body using its mouth, or enveloping the eggs with body loops (Mora 1987). A young yellow anaconda was observed to engulf small fishes using the first technique (A. S. Abe, pers. comm.).

Feeding on avian eggs is regarded as a kind of durophagy (Savitzky 1983), and anacondas also take turtles (Parker and Grandison 1977), another hard-shelled prey ingested intact. The snake-necked turtle, *Platemys macrocephala*, was reported from intestinal contents of *E. notaeus* in the Pantanal (Yamashita et al. 1985), and we observed the turtle *Phrynops vanderhaegei* in the contents of an *Eunectes* rotting carcass (probably *E. murinus*) at another locality in Mato Grosso.

Limpkin nests may be found on bushes up to 1 m above water level in flooded terrain, or near the water in low trees up to 2 m (pers. obs.). Anacondas are known to occasionally climb (Parker and Grandison 1977), and we observed *E. notaeus* foraging at night and taking birds perched on bushes and trees at heights of about 2.5 m. Large nesting colonies of herons and ibises are a common sight in the Pantanal (see Yamashita and Valle 1990), and at these places arboreality would be advantageous for the anaconda. Nestlings and eggs found by *E. notaeus* foraging in trees probably fall prey to this apparently generalized predator.

ACKNOWLEDGMENTS

We thank A. S. Abe, C. Gans, and M. Martins for critically reading an earlier draft of the manuscript; O. Cid at the Santa Inês Ranch for help in the fieldwork and logistical support; the CNPq provided financial support for fieldwork (grants 300092/79 to IS and 831105/89-5 to CS).

AN INVITATION TO JOIN THE HERPETOLOGISTS' LEAGUE

The Herpetologists' League, established in 1936, is an international organization of people devoted to studying the biology of amphibians and reptiles. HL publishes two excellent scholarly journals: the quarterly *Herpetologica*, containing original research papers, essays and book reviews; and the annual supplement *Herpetological Monographs*, containing longer research articles, syntheses, and reviews that can be accommodated in a quarterly journal. The 1992 issue of HM will be a special expanded edition to accommodate publication of a recent symposium entitled "Amphibian Relationships: Phylogenetic Analysis of Morphology and Molecules." Both journals are mailed free of charge to members in good standing of the Herpetologists' League. HL currently provides airlift delivery of its journals (except back issues) to countries outside the United States at no extra charge.

The Herpetologists' League recently embarked on a program to support the publication of books of interest to its members, and to provide members the opportunity to purchase these books for a limited time at specially discounted prices. The initial result of this program was the critically acclaimed "Venomous Reptiles of Latin America." Future projects in this series include the herpetofauna of Baja California, as well as continuing the world checklists project started by the Association of Systematics Collections. Volumes currently in progress include one on snakes and a revision of the 1985 amphibian checklist.

THE IWAKUNI SHIROHEBIS, A GROUP OF ALBINO *Elaphe climacophora*

Albinism in wild populations of snakes is rare or uncommon (Bechtel and Bechtel 1981; Dyrkacz 1981; Hensley 1959; see Satoh and Miyamoto (1987) for records of albino snakes in Japan). The Iwakuni shirohebis are a group of albino *Elaphe climacophora* occurring in a limited area of the city of Iwakuni (34°10'N, 132°13'E), Japan. As far as we know, this is the only instance among snakes where albinism has become established in a wild population. Due to the rarity of this phenomenon, the habitat known to support albino snakes was designated as a natural monument by the Japanese government in 1924. In 1972, the subject of designation was changed to the snakes themselves. Although the Iwakuni shirohebi has been briefly mentioned in English-language literature (Goris and Naganuma 1979; Maki 1931), the accounts were brief and little information was provided concerning the status of the snakes. This paper summarizes the past and present status of this group of snakes.

Among several types of color abnormalities described (Bechtel 1978; Bechtel and Bechtel 1985), the Iwakuni shirohebi consists of amelanistic albinos. All adult snakes are white to yellow. They have golden irises, red pupils, and red tongues. Juveniles have orange blotches on the dorsal and lateral surfaces of the body. The pattern of the blotches is the same as that of wild type juveniles. As the crossing of the albino snakes always produces albino snakes, the gene for albinism is presumed to be allelic.

Little information on historical abundance and distribution exists. In 1924, the residents of Marifu village, one of the predecessors of Iwakuni city, were questioned as to the number of snakes in each block of the village (Yamaguchi Prefecture 1925). The number of snakes was estimated as "no fewer than 1000" and the estimated distribution was about 400 ha (Yamaguchi Prefecture 1925; Watasé 1926). Habitats occupied by snakes were reported to be houses, storehouses, river banks, and stone walls. Active snakes were observed in the streets, gardens, and fields (Watasé 1926). It was not rare to see the albino snakes in human residences (Yamaguchi Prefecture 1925).

Since the 1970s, the city of Iwakuni has appealed to its citizens to report occurrences of albino snakes. The number of snakes reported is declining; the average number per year (followed by SD and range) was 22.6 (12.3, 12-40), 8.8 (3.6, 4-12) and 4.8 (3.0, 0-8) for 1974-1978, 1981-1985, and 1986-1990, respectively.

The authorities and citizens of Iwakuni city are concerned about the decreasing number of albino snakes. The city of Iwakuni and the Society for the Conservation of the Iwakuni shirohebi, organized by volunteers, are making great efforts to conserve the shirohebi. To breed the snakes, they constructed an indoor breeding facility (total floor space of 240 m^2) and three outdoor pens (total space of 1560 m^2). Financial aid from the Japanese government was obtained for construction of one of the outdoor enclosures. In general, the adult snakes are allowed to breed at random in the pens, and emerging hatchlings are collected and raised in the indoor facility. Juveniles are released into the outdoor pens after three years. Approximately 400 snakes are maintained in these facilities.

The normal type of *E. climacophora* is abundant in the city. Studies are under way in an attempt to elucidate the circumstances surrounding the establishment and maintenance of high-frequency albinism in *E. climacophora*.

This study was sponsored by Iwakuni city and the Society for the Conservation of the Iwakuni shirohebi.

POINTS OF VIEW

WHEN IS AN INTRODUCTION NOT AN INTRODUCTION?

Imagine my surprise when I saw a distributional spot for *Eleutherodactylus coqui*, a Puerto Rican frog, in the New Orleans, Louisiana area in the recently published *A Field Guide to Reptiles and Amphibians of Eastern and Central North America* (Conant and Collins 1991). As the coauthor responsible for the amphibian accounts in *The Amphibians and Reptiles of Louisiana* (Dundee and Rossman 1989), I felt embarrassed that I had missed such a record in the literature. I checked the text of Conant and Collins and found that it stated that the frog was introduced at New Orleans. Reference to the locality was given by Schwartz and Henderson (1988), with Frost (1985) given as the source. In Frost I found that the original report was credited to Rivero (1984). Neither Zoological Record or Biological Abstracts had the Rivero paper listed—neither abstracts from the Journal of the Bromeliad Society.

I felt vindicated for my oversight, but nevertheless I examined the Rivero article and found that he had said, "For more than four years, a few males have been calling from bromeliads in Jeanne Garman's garden in New Orleans." I contacted Mrs. Garman in July 1991 and the whole story emerged. Although she had never met Rivero nor been to Puerto Rico, she had corresponded with him regarding bromeliads. Rivero sent her five male *Eleutherodactylus coqui*; two arrived alive on 12 October 1979 and were released in her greenhouse where she kept bromeliads. The greenhouse was open to the outside in warm months, but closed in winter. After six to eight months, only one male survived and continued his singing for 3-4 yrs. He is gone now.

Rivero has confirmed in a letter to me (31 July 1991) that he avoided the possibility of an introduction by sending Mrs. Garman only males. Therefore, although the record was valid, the "population" did not constitute a viable introduction; it did not pose the possibility of reproductive success, nor did it prove that outdoor survival was possible. A true introduction should be one in which natural survival without the intervention and support of man has occurred. Otherwise we could justifiably say that species that survive outdoors in zoos or game farms constitute introductions.

Accidental introductions will occur; deliberate ones should be avoided in the interests of ecological integrity. The Miami, Florida area is one where many introductions have probably been deliberately made, and recent distributional records suggest that herpetologists, both amateur and professional, may have had a hand in the spread of exotic species. Having exotic species around one may be exciting, but it is bad policy, thus the herpetological community should practice proper restraint.

TECHNIQUES

RELATIONSHIP BETWEEN GOPHER TORTOISE BODY SIZE AND BURROW WIDTH

Gopher tortoises (*Gopherus polyphemus*) occur in the coastal plain of six southeastern states (Auffenberg and Franz 1982). They dig long, deep burrows in habitats with well-drained, deep sandy soils. A high correlation exists between tortoise straight-line carapace length and burrow width (Alford 1980; Hansen 1963; Martin and Layne 1987). Because of this correlation, measurements of burrow widths are used to estimate the size class distribution of tortoises in a population (Alford 1980; Cox et al. 1987). No studies, as far as we know, offer an explanation for this correlation, however. A probable misconception is that the correlation derives from a causal relationship; specifically, burrow width is maintained so that a resident tortoise can turn around anywhere in its burrow. This assumption lacks verification. As no good alternate explanation seems to exist, we sought data to provide a functional explanation for the relationship between carapace length and burrow width.

During the spring of 1991, we watched tortoises digging burrows in a central Florida sandhill (see Myers 1990 for a habitat description). We noted that only the forearms of a tortoise extend beyond the margin of the shell during burrow excavation. We noted also that tortoises do not use both forearms simultaneously as they excavate their burrows, but pivot from side-to-side as they alternate the power stroke. Based upon our observations of tortoise digging behavior, we hypothesized that some measure of "burrowing diameter" of a tortoise is related to its carapace length, and that carapace length, therefore, is merely a useful index of a tortoise's burrowing diameter.

To test our hypothesis, we captured 75 tortoises inhabiting the University of South Florida Ecological Research Area in Tampa. Tortoises were captured by placing concealed buckets at the burrow mouths. By examining tortoise footprints, we were able to determine that individuals were captured as they exited their burrow. We used a relatively large sample of tortoises to accommodate the possibility that some tortoises may have been paired with burrows that they had not constructed.

The width of the burrow occupied by each tortoise was measured at a depth of 50 cm with calipers constructed from two meter sticks hinged together with a bolt 50 cm from the end. We inserted the calipers into each burrow, and measured the width across the open arms (Martin and Layne 1987). For each tortoise, we measured its greatest straight line carapace length, greatest carapace

width, body width (at the level of the pectoral girdle, across the plastron at the distal union of the humeral and pectoral scutes), and forearm length (from the distal end of the humerus to the tip of the longest claw) (Fig. 1).

We calculated the burrowing diameter of a tortoise in two ways. First, we doubled its forearm length and added the result to its body width (called the "shoulder-feet" method). Use of this measure of burrowing diameter assumes that a tortoise maintains a relatively central position as it digs its burrow, regardless of whether it uses its arms singly or in tandem. Second, we subtracted body width from carapace width, divided the result by 2, and then added the quotient to the sum of body width plus forearm length (called the "carapace-foot" method). Use of this measure of burrowing diameter assumes that a tortoise pushes itself against the right side of the burrow as it digs with its left forearm and vice-versa.

In almost all cases, carapace length was smaller than corresponding burrow width. Likewise, both methods of calculating burrowing diameter generally yielded a smaller value than corresponding burrow width. For example, one of our tortoises that was captured from a burrow measuring 150 mm, had a carapace length of 131 mm, a shoulder-feet burrowing diameter of 149 mm, and a carapace-foot burrowing diameter of 124.5 mm. The carapace-foot method used to calculate burrowing diameter produced values that were 15-20% smaller than those produced by the shoulder-feet method, and 20-25% smaller than the burrow widths. These findings, coupled with our observations of digging behavior, suggested to us that the shoulder-feet method is the more accurate way of matching dimensions of the tortoise that are relevant to the mechanics of digging with the resulting burrow. We focus our attention, therefore, on the shoulder-feet method, and all subsequent references to burrowing diameter refer to this method. We suggest, however, that direct observation is necessary to confirm the precise measurements of tortoises that reflect their burrowing behavior.

Burrow width and burrowing diameter were correlated positively ($r = 0.93$, $p < 0.001$, $n = 75$). We related burrowing diameter to carapace length for the 75 tortoises with geometric mean regression (GMR). Standard regression theory assumes that the X variable (burrowing diameter in this case) is measured without error; only the Y variable (carapace length in this case) has associated measurement error. Geometric mean regression (Ricker 1984) relaxes this assumption and allows calculation of a regression line when measurement error is present in both the X and Y variables. The GMR equation relating carapace length (CL) to burrowing diameter (BD) is: $CL = -2.46 + 0.915BD$ ($r = 0.987$, $p < 0.001$, $n = 75$). These findings indicate that carapace length and burrowing diameter are highly correlated and, although the slope of the relationship is not 1.0 ($t = 7.13$, $p < 0.001$, $df = 73$), burrowing diameter and carapace length are quite similar for tortoises of any size.

We conclude that burrow width is a reliable indicator of tortoise carapace length because of the correlation between carapace length and the morphological components involved in burrow construction (burrowing diameter). The presumed causal relationship between carapace length and burrow width may not exist, and therefore, one need not take an adaptationist position to explain their correlation. The ability of a gopher tortoise to turn around in any portion of its burrow may only be a fortuitous byproduct of its morphology (i.e., burrowing diameter) and not a primary force in determining the width of its burrow.

HERPETOLOGICAL HUSBANDRY

AD-LIBITUM FEEDING RATES, GROWTH, AND SURVIVAL OF CAPTIVE-HATCHED CHAMELEONS (*Chamaeleo pardalis*) FROM NOSÉ BE ISLAND, MADAGASCAR

Wild-caught Old World chameleons are relatively hardy in captivity, if one obtains healthy young animals, treats them for parasites, and utilizes proper species-specific husbandry techniques (see Bustard 1989, DeVosjoli 1990, Ferguson and Blades 1991, for description of these techniques). Several species have bred in captivity. Raising captive-hatched or -born juveniles to maturity and obtaining successful reproduction from them is quite another matter. Successful second-generation captive breeding has been reported (McKeown 1991, Obst et al. 1988, Van Mater 1971) but high mortality followed by poor reproduction of captive-raised adults is the general rule. Little is known of the energy, nutritional, and light requirements of juvenile chameleons, and given the diversity of this group these requirements are likely to differ significantly among species.

The Malagasy panther chameleon (*Chamaeleo pardalis*), and especially the population from Nosé Be Island off the northwest tip of Madagascar, seems to be one of the most hardy chameleons in captivity. Some keepers have reported males that live up to 8 yrs in captivity (De Vosjoli 1990). I have maintained several wild-caught adult males for over three years with no mortality. Females cycle continuously, producing a clutch of 15-35 eggs every 6 to 8 weeks. In this report, I provide information on just how much a panther chameleon will eat under ad-libitum food conditions throughout its growth cycle. Although I have not conducted experiments, I, like others (De Vosjoli 1990), have the distinct impression that underfed small juvenile chameleons are highly susceptible to sudden mortality even though they do not appear emaciated. Simply providing sufficient food may prevent the high juvenile mortality that keepers frequently observe.

I conducted a growth study of a cohort of 16 hatchling *C. pardalis* in my laboratory at TCU from January 1990 through March 1991. Chameleons were housed individually in 1.3 l plastic fish bowls from hatchling size until about one-quarter grown (10 cm TL). They were then transferred to 7.9 l plastic terraria (Pet Habitats, Fritz Co.) until maturity (20-25 cm TL). Males were then transferred to 13.2 l terraria until they approached full size (35-40 cm TL), at which time they were moved to larger enclosures (50 l aquaria or larger). Throughout the study, cage furniture consisted only of dead twigs for perching and plastic vials or cups containing insect food and vitamin/mineral powder taped to the cage floor. Cage walls were sprayed daily, and cages were thoroughly cleaned every 10-14 days. Food containers were cleaned daily as necessary. Cage temperatures were maintained from a nighttime low of 19-23°C to a daytime high of 30-33°C. There were minor, seasonal variations of temperature (especially lows) but there was little variation from cage to cage. However, cage positions were rotated daily along the 2.5 m desk top where the cages were kept to equalize minor "position effects." Fluorescent lighting on a 12 h photoperiod (Vitalites, Durotest Corp.) was positioned 15 cm above the open cage tops. This was far enough from the animals to prevent utilization of the lamps as a heat source. Thus, their body temperatures (periodically monitored) closely matched that of the general area, which was monitored daily with minimum-maximum thermometers. Appropriate-sized crickets (*Achaeta*), mealworms (*Tenebrio molitor*), or super worms (*Zophobas morio*) were introduced daily in weighed quantities to ensure uneaten excess at feeding time the next day. Vitamin-mineral supplement was continually available in the bottom of the vial or cup and was changed with each feeding. The supplement was a mixture of 1/2 Reptivite (Zoo Med, Santa Ana, California) and 1/2 calcium carbonate. The mixture was stored in a freezer at -10°C. Residual insects were weighed each day and discarded before introducing new food. Insects lost weight in the vials due to dehydration and tissue metabolism. A control feeding dish (containing insects and vitamin/mineral powder, but not exposed to chameleons) indicated this weight loss to average 10-15% per day. When determining mass of food eaten (mass of food on day 1 minus residual mass of food on day 2), residual mass was corrected for weight loss.

Table 1 indicates the mass of insect food eaten by juveniles at different ages under these conditions. Juveniles ate 4 to 6 times their body mass per month, or about the equivalent of the body mass per week during the first four months. The amount of food eaten increased dramatically during the first five months, then leveled off as the animals reached maturity. Table 2 converts insect mass into numbers of insects of each size fed to the chameleons. Note that for the first two months of life large numbers of small crickets were consumed daily (up to ca. 3 dozen per day).

All 16 of these animals showed no developmental abnormalities. All reproduced beginning at five months of age and continued to reproduce throughout the experiment. After 18 months, all but two of the ten females had died after producing from one to five fertile clutches of eggs. Death of each occurred while gravid or shortly after laying a clutch of eggs. A pathology report on one female indicated some problems with calcium imbalance (metastatic calcification of soft tissues). All of the fertile eggs produced by these animals developed to full-term embryos, but to date less than 10% have hatched; most died at full term. Clearly these laboratory conditions are not perfect for *C. pardalis*. Some fine-tuning of nutrition, lighting, and other environmental factors is needed. Results thus far strongly indicate that large amounts of food must be provided to

Table 1. Mean mass of insects eaten by captive-hatched *Chamaeleo pardalis* at each of their first 9 months of life. Mean mass of chameleons at the beginning of the month is give. Male and female chameleons diverged significantly in size by age 7 months (repeated measures ANOVA, probability of a significant interaction between sexes of mass vs. time <0.001). Amount of food eaten was not significantly different for the sexes but gravid females tended to eat less than males or non-gravid females. Double values separated by a "/" indicate male/female.

RECENT POPULATION CHANGES

POPULATION CHANGES IN *Atelopus* SPECIES OF THE CORDILLERA DE MÉRIDA, VENEZUELA

The Venezuelan Andes, with its complex arrangement of diverse high montane ecosystems, support a group of closely related, brightly colored bufonids in the genus *Atelopus*. Six such species have been described from these mountains, and five of them (*A. carbonerensis, A. mucubajiensis, A. oxyrhynchus, A. pinangoi, A. sorianoi)* are reported from páramos and cloud forest in the Venezuelan Cordillera de Mérida. Reports on their abundance dating as early as 1922 indicate that these anurans were historically among the most prominent and ubiquitous species in their respec-

Table 2. Mean number of insects eaten by captive-hatched *Chamaeleo pardalis* at each of their first 9 months of life. Values were obtained by dividing values from Table 1 by mean mass of 5 samples of 10 insects each (see values of mean mass in column 1). SC = small-sized crickets, MC = medium-sized crickets, MMW = medium-sized mealworms, SW = superworms.

Chameleon Age (months)	1	2	3	4	5	6	7	8	9

tive environments. The field notes of M. A. Carriker archived at the University of Michigan Museum of Zoology (UMMZ) indicate that he observed at least 27 *A. oxyrhynchus* (= *A. carbonerensis*, sensu La Marca 1983), 25 of which were collected in a "very small" area. The reports of other investigators also emphasized the historical abundance of this toad. Rivero (1972) stated that "a hundred can be collected in less than an hour." Durant and Dole (1974a), in an ecological study performed at the type locality, captured, marked, and released 750 *A. carbonerensis*. Censuses had been conducted in 12 out of 13 continuous months with a range of from 5 to 69 individuals per census. The abundance of *A. carbonerensis* also seems to have characterized the other species of Venezuelan Andean *Atelopus*. We observed large numbers of individuals (roughly 50 and 100, respectively) of *A. oxyrhynchus* in June of 1978 at Monte Zerpa (in ca. 10 min collecting effort), near the city of Mérida, and of *A. sorianoi* in June of 1988, at its type locality (in ca. 30 min of observation).

We are concerned that these once seemingly abundant anurans now appear to have their numbers drastically diminished. From March to November 1990, we made 34 field excursions, totaling 40 days (for a total of ca. 320 man h of search effort), to places where formerly we had observed large numbers (usually ten or more individuals) of five Venezuelan Andean *Atelopus*. Our trips were discouraging, for even with this significant search effort, we only found one specimen of *A. mucubajiensis*, and two of *A. sorianoi*.

Declines in populations of Venezuelan Andean *Atelopus* appear not to be an isolated problem. The decline of amphibian populations appears to be a worldwide phenomenon, and various hypotheses have been offered to account for the declines (Blaustein and Wake 1990, Phillips 1990, Wyman 1990). Habitat destruction accounts for reductions in frog populations in disturbed habitats. However, for those places that have not experienced obvious environmental degradation, the following factors have been proposed as causative agents: global climatic change, pollution, ultraviolet radiation, and habitat fragmentation (Wyman 1990). Below, we briefly discuss several factors that may account, singly or collectively, for the observed declines in populations of Venezuelan Andean *Atelopus*.:

1) Destruction of natural habitats.—Several *Atelopus* species are endemic to the Venezuelan Andes and in such montane environments even slight habitat disturbances may cause severe changes. Habitat destruction may be having a considerable impact on populations of *A. carbonerensis*, *A. oxyrhynchus*, *A.pinangoi*, and *A. sorianoi*. Increases in agrofarming acreage have reduced historic forests to small isolated patches, one of which holds the only known population of *A. sorianoi*. The very small geographic ranges of these highly restricted endemics places them at considerable risk if further reduction of this forested area occurs. At present, the areas where some of these species occur are not protected by Venezuelan law. In the Rio Mucujún Basin, where *A. oxyrhynchus* was frequently seen by us in the early 1980s, agriculture and cattle farming have increased steadily over the past two decades. Likewise, the places where *A. carbonerensis* and *A. pinangoi* occur have been subjected to extensive human modification.

2) Floods.—Floods may adversely impact Venezuelan *Atelopus*; most of these frogs occur and breed in places of high precipitation (e.g., montane cloud forests). Duellman and Trueb (1986) reported a flood affecting *Atelopus mindoensis*. In a mountain stream in Ecuador, they observed 77 individuals of *A. mindoensis*; "after a flash flood had scoured away nearly all streamside vegetation," they were able to find only two specimens. At least one population of an undescribed *Atelopus* from a cloud forest in the Venezuelan Andes may have been similarly affected by flash floods. According to Alberto Juárez and Isaac Goldstein, frogs were common in October 1989 (10 individuals collected, ca. 10 others seen). We were unable to find a single frog when we visited the locality in July 1990. However, we noticed that local flooding in April 1990 had scoured away the vegetation alongside the "quebradas" (cascading mountain streams).

3) Road kills.—Reports of road kills are rare among Neotropical amphibians. Among Venezuelan *Atelopus*, Rivero (1972) reported on "dozens of dried, squashed" *A. carbonerensis* "along the road from Mérida to La Azulita," and "numerous squashed specimens [of *A. mucubajiensis*] along the roads" (both reports probably are from near their respective type localities). Further, in June 1988, the junior author observed 42 road-killed *A. sorianoi* near its type locality. This number represents about 44% of the total observed in one day at that locality; 53 living individuals were encountered. The high percentage of road kills for an anuran with such a restricted distribution is of concern.

4) Overcollection.—Overcollection has not been addressed in available literature on *Atelopus*, but this activity may account for a decrease of certain vulnerable endemic species. A cursory review of Venezuelan *Atelopus* in museums in the United States and Venezuela was enlightening. The taxa most collected have been *A. carbonerensis* (nearly 400 specimens, of which 154 are "paratypes"), *A. oxyrhynchus* (nearly 160), and *A. mucubajiensis* (nearly 140). We believe these data are not representative of the total number of individuals collected for scientific purposes. In the available literature, evidence exists that many individuals of these taxa were collected but never deposited in any collection. Piñero (1985) collected 28 *A. oxyrhynchus* in Monte Zerpa, near the city of Mérida; Durant and Dole (1974b) collected 63 *A. carbonerensis*; and Durant (1976) collected 104 *Atelopus*, 33 from "La Carbonera" (*A. carbonerensis*), 51 from "La Culata" (*A. oxyrhynchus*) and 20 from "Mucubají" (*A. mucubajiensis*). Piñero (pers. comm.) never deposited her frogs in collections; they probably are lost now. Perusal of lists from museums in the United States and Venezuela, and herpetological collections and catalogs at the Universidad de Los Andes in Mérida, reveal the following total numbers of *Atelopus* deposited either by Durant or both Durant and Dole: 4 *A. carbonerensis*, 14 *A. mucubajiensis*, and 33 *A. oxyrhynchus*.

Casual collectors attracted by these colorful frogs, and some commercial dealers, are probably also responsible for taking some *Atelopus* species. We are aware of at least three private dealers who offered Venezuelan *Atelopus* for sale in Germany and the United States in 1982 and 1989.

Three other factors, albeit less well supported than those mentioned above, may also play significant roles in the observed population declines:

5) Climatic changes.—We lack precise information on such changes in the Venezuelan Andes, but reduction in forest cover may contribute to increasing drought susceptibility in the entire region. This may not be the only effect of

deforestation. Increased run-off with high erosion potential can produce stronger floods that increase the probability that susceptible environments along the water courses where *Atelopus* occur will experience scouring. Other climatic factors may also be important. Blaustein and Wake (1990) noted that there "is little evidence for declines of amphibians inhabiting low-equatorial (within 10° north or south of the equator), low altitude regions." Hobart M. Smith (in litt.) suspects that radiation (which is directly correlated with altitude) may be a significant factor explaining population declines at altitudes above 1000 m. Ultraviolet radiation has been implicated in some declines (Wyman 1990).

6) Pollution.—We lack information on the effect of pollution on the Venezuelan Andean frog fauna, but biocides washed from agricultural fields into streams probably affect species living along those environments. *Atelopus* species may be affected by such pollutants. DDT, parathion, and other chemicals whose use is illegal in developed countries but still sold to third world countries are but a few examples of biocides employed in the Venezuelan Andes. The notion that contamination by heavy metals and pesticides may play a role in the decline of some species has been noted previously (Phillips 1990).

7) Introduced species.—At least two introduced taxa may contribute to declines among Venezuelan *Atelopus*. Conifers, especially members of the genus *Pinus,* have been introduced in some páramo (Ohep and Herrera 1985) and cloud forest (Mendoza 1969) environments where, respectively, *A. mucubajiensis* and *A. carbonerensis* occur. Larcher (1983) provided evapotranspiration rates (as percentages of precipitation) for some coniferous forests of flatlands in northeastern Europe (with rates ranging from 60 to 65%) and in some mountain forests in Europe and North America (ranging from 25 to 52%). Larcher's data suggest that coniferous forests have higher evapotranspiration rates compared to native montane cloud forests. Research is needed to ascertain whether Venezuelan Andean introduced conifers, mostly *Pinus* from Central America (CONARE 1977; Lamprecht 1961) contribute to a humidity deficit in Andean forests. These conifers may also depress pH of local ground water through acidic runoff from nearby pine plantations. Levels of pH in conifer forests are typically quite low, and the distribution and abundance of frogs elsewhere has been shown to be correlated with soil pH (Wyman 1988, 1990).

Introduced trout (*Salmo* and *Onchorhynchus*) may also pose a potential threat to *Atelopus* populations. We have observed trout at both *A. mucubajiensis* and *A. pinangoi* localities, where they may prey on *Atelopus* larvae. Hayes and Jennings (1986) discuss the relationship between predation by fish and decline of anuran populations.

Atelopus endemic to the Venezuelan Andes, historically common, are declining in an alarming manner. Because of this, we urge the Venezuelan government and appropriate international organizations to confer protected status and encourage their study.

ACKNOWLEDGMENTS

We are indebted to Hobart M. Smith (University of Colorado) for kindly sharing his personal comments on this topic. Arnold G. Kluge (UMMZ) generously provided the senior author with Carriker's field notes. Grants S1-2053 from CONICIT (Consejo Nacional de Investigaciones Científicas y Tecnológicas de Venezuela) and Fo. 223-89 from CDCHT (Consejo de Desarrollo Científico, Humanístico y Tecnológico de la Universidad de Los Andes), both to the senior author, provided funds for field studies. The Ministerium für Wissenschaft und Forschung of Austria provided financial support to the junior author. Data for the undescribed *Atelopus*, gathered under a grant from the Wildlife International Conservation [Fund] of the New York Zoological Society to Isaac Goldstein, were graciously supplied by Goldstein and Alberto Juárez. The manuscript has been greatly improved by the comments of three anonymous reviewers.

LIFE HISTORY NOTES

CAUDATA

AMBYSTOMA MACULATUM (Spotted Salamander). **PREDATION.** Overland migration exposes ambystomatid salamanders to risks not encountered in the underground habitat, e.g., desiccation (Holland et al. 1990. Southwest. Nat. 35:217-220). On 14 March 1988 at ca. 1500 h, I found 21 dead *Ambystoma maculatum* scattered around the periphery of a small, rain-filled pool. The pool (2 X 2.5 m, maximum depth = 1.0 m) was located in Blue Valley, on the southern escarpment of the Blue Ridge Mountains in the Nantahala National Forest, North Carolina at an altitude of 780 m. *Rana sylvatica* also breeds in this pool.

All carcasses consisted of only the pelvic girdle (including the hindlegs) and tail. Cloacal inspection allowed 18 of the carcasses to be sexed, of which 16 were female. Males of *Ambystoma* typically arrive at breeding ponds before females (Bishop 1941. Bull. New York State Mus. 324:1-365; Pfingsten and Downs 1989. Bull. Ohio Biol. Survey, New Ser. 7(2):1-315). I searched the pool using a dipnet, however, and found one female. The preponderance of females among the carcasses and the absence of males in the pool suggests that the females arrived first at this pool.

No sign of a predator was found in the vicinity of the pool. Short-tailed shrews are present locally and can prey upon salamanders. However, the large number of salamanders killed suggests that the predator may have been a larger mammal. Raccoons, opossums, weasels, and minks are present in the area and represent likely predators.

This manuscript benefited from comments from R. C. Bruce and was written while the author was supported by Louisiana Board of Regents Doctoral Fellowship LEQSF (1988-1994) - GF-15.

Submitted by **CHRISTOPHER KING BEACHY**, Department of Biology, Western Carolina University, Cullowhee, North Carolina 28723, USA. Present address: Department of Biology, P.O. Box 42451, The University of Southwestern Louisiana, Lafayette, Louisiana 70504-2451, USA.

AMBYSTOMA TEXANUM (Smallmouth Salamander). **ALBINISM.** Two albino *Ambystoma texanum* (Fig. 1) were collected on 19 and 20 April 1984 by Ricky G. Jones and Bill Arntz. Both individuals possessed pink eyes characteristic of total albinism (sensu Nero 1954. Auk 71:137-155). To our knowledge, this is the first reported instance of total albinism in *A. texanum* (Dyrcacz 1981. SSAR Herp. Circ. 11. 31 pp.). The specimens were collected from an abandoned swimming pool in the Britton area of Oklahoma County, Oklahoma that was partially filled (1 m depth) with turbid rainwater. The pool has since been destroyed and removed. Snout-vent lengths of the specimens after preservation in 10% formalin were 71 and 70 mm. The two albinos were found together with two normally pigmented conspecifics.

I thank Marvin L. Mays and Victor

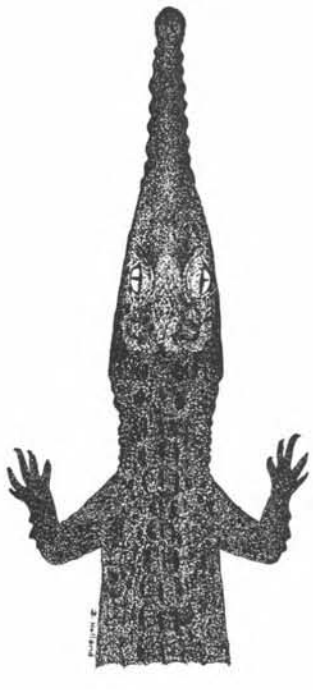

Figure 1. Albino *Ambystoma texanum* from Oklahoma County, Oklahoma.

Hutchison for identifying the specimens, and Troy A. Baird for helpful suggestions on the manuscript. The specimens have been deposited in the Oklahoma Museum of Natural History herpetology collection.

ANURA

OSTEOPILUS DOMINICENSIS (NCN). **BEHAVIOR.** On 31 May 1991 at the Acuario Nacional, Santo Domingo, Distrito Nacional, and again on 3 June 1991 near the Hotel Guarocuya, Barahona, Barahona Province, República Dominicana, we observed one and two instances, respectively, of *Osteopilus dominicensis* making use of trunk cavities in a manner similar to *Hyla chrysoscelis* in Tennessee (Ritke and Babb. 1991. Herpetol. Rev. 22(1):5-8).

The frog from the aquarium grounds (SVL ca. 60 mm) was in a trunk cavity of a coconut palm (DBH = 32 cm), 168 cm above the ground, dimensions (w x h) of the opening were 7.5 x 2.5 cm, dimensions (w x h x d) of the cavity were 5 x 7 x 10 cm. A. Schwartz (field notes) described finding a large female (SVL = 77 mm) in a "H_2O filled cavity of 4" diameter palm" (Haiti, Dept. l'Ouest, beach just w. Grand Goôve, 30 July 1971). Both of the Barahona specimens were females (SVL = 59 mm, 63 mm) and were found in knotholes of almond trees (DBH = 110 and 85 cm). Heights and dimensions of the cavities were 100 cm, 8 x 5 cm, 9 x 6 x 22 cm, and 125 cm, 9 x 5 cm, 9 x 5 x 20 cm, respectively. In each instance the cavity used by these frogs held water or was very moist. Similar holes (N = 4) in Barahona, but with drainage and therefore drier, were not occupied by *Osteopilus* during the two-week period of observation. The two frogs from Barahona were collected on 10 June. The vacated holes had not been reinhabited by 16 June, despite conditions (almost nightly periods of showers) presumably conducive to anuran movements.

The frog from the aquarium grounds was not collected, but the two specimens from Barahona were deposited in the Bobby Witcher Memorial Collection (BWMC 04592-3), Avila College. The Schwartz specimen (Albert Schwartz Field Series, ASFS V36674) is in the Museum of Natural History, University of Kansas.

We wish to thank Sixto and Ivonne Incháustegui, who provided assistance in the Dominican Republic. José A. Ottenwalder of the Parque Zoológico Nacional facilitated opportunities for field work. Permits were graciously provided by Emílio A. Bautista M., Director, Departamento de Vida Silvestre, República Dominicana.

SMITH,** Division of Allergy & Rheumatism, University of Kansas Medical Center, Kansas City, Kansas 66103, USA, **ROBERT POWELL,** Department of Natural Sciences, Avila College, Kansas City, Missouri 64145, USA, **PETER A. ZANI,** Department of Zoology, Miami University, Oxford, Ohio 45056, USA, and **AMY LATHROP,** Museum of Natural History, University of Kansas, Lawrence, Kansas 66045, USA.

PTERNOHYLA DENTATA (Upland Burrowing Treefrog). **MATING CALL.** The call of *Pternohyla dentata* was recorded at the edge of a small pond in farmland at Potrero del Campo Santo, 1 km NW of Villa Hidalgo, Jalisco, México. The specimen is deposited at Museo de Zoología, Fac. de Ciencias, UNAM (No. MZFC 04874). A copy of the tape is on file at the National Museum of Natural History, Smithsonian Institution. Air temperature was not recorded; the call was recorded early at dusk.

The call consists of a series of notes given at a rate of 150/min (Fig. 1). The average note duration is 0.20 s and the average internote duration is 0.21 s. The energy is broadcast in three frequency bands, two strong bands at 400-475 Hz (fundamental?) and 1900-2200 Hz (5th harmonic?) and a weak band at 3200-3500 Hz (9th harmonic?). The level of background noise precludes wave form analysis to determine whether the call is pulsatile.

Pternohyla dentata has a faster call rate and lower fundamental frequency than *P. fodiens* as described by Trueb (1969. Cat. Amer. Amphib. Rept. 77:1-4), although both have broadcast energy around 2000 Hz.

W. Ronald Heyer helped with the analysis of the call. JVD wishes to thank Gustavo E. Quintero Díaz and Vicente Esparza Soto for field assistance. Participation of OFV was possible due to DGAPA UNAM No. IN201789.

Submitted by **JOEL VÁSQUEZ-DIAL** and **OSCAR FLORES-VILLELA,** Museo de Zoología, Fac. de Ciencias, UNAM, A.P. 70-399, México, D.F. 04510, México

UPEROLEIA LAEVIGATA (NCN). **BEHAVIOR.** The behavior of Australian frogs is relatively unstudied. While photographing a specimen of the myobatrachid *Uperoleia laevigata* caught in Terrey Hills near Ku-ring-gai Chase National Park, N.S.W., I observed a previously undescribed defensive behavior pattern.

As I approached from the side to reposition the frog for a photograph, it inflated its body slightly and tilted toward me. This tilting action caused the bright orange patch present on the front of the hind limb on the opposite side from me to be exposed. Subsequent prodding of the frog with a stick failed to cause it to jump; instead, it continued the "tilting" behavior.

Puffing up the body by inflating the lungs is a common defensive behavior among heavy-bodied anurans such as species of *Bufo* (Duellman and Trueb

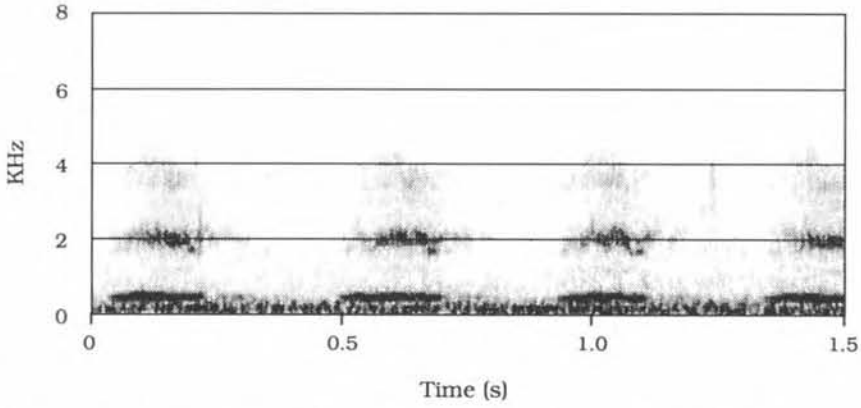

Figure 1. Audiospectrogram of the call of *Pternohyla dentata* from Jalisco, México.

1986. Biology of Amphibians, McGraw-Hill, New York, 670 pp.). In some *Bufo* species this is accompanied by a lateral tilting of the body towards the predator (Hanson and Vial 1956. Herpetologica 12:141-149). P. Harlow (pers. comm.) suggests that *U. laevigata* is toxic and the presence of enlarged parotoid glands (Tyler et al. 1981. Aust. J. Zool. Suppl. Ser. 79:1-64) supports this suggestion. The orange patches on the front of the thigh in *U. laevigata* may represent hidden aposematic coloration similar to that seen in *Bombina variegata* (Duellman and Trueb, op. cit.). There is, however, no evidence at present to support this speculation. Further work on defensive behavior and toxicity of Australian frogs appears warranted.

I thank R. Shine, P. Harlow, L. Schwartzkopf, and F. Lemckert for comments on the manuscript.

CROCODYLIA

CROCODYLUS ACUTUS (American Crocodile). **SOCIAL BEHAVIOR.** Crocodilians have some of the most highly developed social behaviors of any reptile. Many of the advertisement displays used by crocodilians involve stereotyped body posturing, headslapping, and loud vocalizations referred to as roars or bellows. Nevertheless, the one published study of *C. acutus* social behavior (Garrick and Lang 1977. Am. Zool. 17:225-239) did not verify the presence of a vocal component to the advertisement display.

While maintaining a pair of *C. acutus* in Venezuela (Funa Pecuario Masaguaral; 8°34'N, 67°35'W) for captive breeding purposes, I had the opportunity to observe male advertisement displays on six occasions (7 April, 28 September, 5 December 1988, 13 February, 21 March, and 18 April 1989). The timing of these displays largely coincided with the species' courtship (November–January) and nesting (February–March) seasons on Masaguaral. The male (3.3 m TL) entered a head-elevated, tail-arched posture in shallow water, similar to the posture described in Garrick and Lang (op. cit., Fig. 2f) for *C. acutus* subaudible vibrations. From this posture, the male proceeded to headslap 2 to 3 times, then produced 1 to 5 loud roars (mean = 2.5 roars per advertisement display). All displays occurred in the morning (0656 to 0857 h) and were very similar to the adverisement display of male Orinoco crocodiles (*C. intermedius*) that were housed at the same crocodile breeding facility (pers. obs.). The female (2.8 m TL) never produced headslaps or roars.

LACERTILIA

ANOLIS CHLOROCYANUS (Hispaniolan Green Anole). **BEHAVIOR.** On 18 June 1991, on natural vegetation at the Casa de Campo resort complex near La Romana, La Romana Province, República Dominicana, we observed two instances of aggressive behavior in *Anolis chlorocyanus*. On the first occasion at 1410 h, ca. 1.5 m above the ground on a small tree (DBH = 10 cm), a large male (SVL estimated by eye at ca. 65 mm) was observed with the entire head of a female *Anolis cristatellus* (SVL ca. 40 mm) in its mouth. During the 2-3 min span of observation, the *A. chlorocyanus* made concerted efforts to reposition the *A. cristatellus* in an apparent effort to facilitate swallowing. The latter was struggling frantically, thrashing its entire body. Finally, during one attempt at realignment, the *A. cristatellus* managed to escape, fell to the ground, and rapidly disappeared into the undergrowth. We did not observe initiation of the encounter, and the *A. cristatellus* appeared to be too large for consideration as food, but we assume that the *A. chorocyanus* was treating the *A. cristatellus* as prey. Aggression or territorial defense, however, cannot be ruled out.

The second observation of aggressive behavior was between two large (ca. 65 mm SVL) male *A. chlorocyanus*. At 1430 hrs, at a height of ca. 3 m on a small tree (DBH = 18 cm), one male was observed with its mouth completely encompassing the head of the other. Again, initiation of the encounter was not observed, and we assumed it to be a territorial dispute gone awry (interlocking jaws being a much more common situation). After less than two minutes, the latter individual managed to escape and fell to the ground. This lizard immediately climbed an adjacent tree to the same height as that still occupied by the first animal, then dewlapped repeatedly before further ascending the tree, precluding additional observation. Interestingly, the male in the grasp of the other had assumed a bright blue color, in vivid contrast to the bright green of the second individual and that normally associated with active males. It retained this color throughout the period of observation.

Submitted by **ROBERT POWELL** and **JOHN S. PARMERLEE, JR.**, Department of Natural Sciences, Avila College, Kansas City, Missouri 64145, USA.

SERPENTES

AGKISTRODON PISCIVORUS PISCIVORUS (Eastern Cottonmouth). **DIET.** On 4 May 1991 at ca. 1600 h, while on a herpetology class field trip, we discovered a dead red-bellied water snake (*Nerodia erythrogaster erythrogaster*, ca. 1.3 m TL) lying near the shore at Steel Creek Bay, a wetland on the Savannah River Site in Barnwell County, South Carolina. The snake was on land, ca. 1 m from the water's edge and 1 m from the edge of a dirt road bordering the wetland. No visible cause of death was apparent, but the snake obviously had been dead for several hours based on the odor. The snake was placed alongside the road for the class to examine and left in this spot.

After dark, at 2100 h, we stopped at the same location to show a new member of the field trip the dead water snake. To our surprise the water snake was found in the water being consumed by an *Agkistrodon p. piscivorus* (also ca. 1.3 m TL) which had swallowed the first several centimeters of the dead snake.

When several students got out of the vehicle, the cottonmouth quickly released its grip and swam away. We again put the dead snake back on land when we left the area. Upon returning to the site at 2130 h we found the *A. piscivorus* now on land with ca. 30 cm of the water snake in its mouth. During the next 20 min the *A. piscivorus* released its hold and backed off of the water snake completely two times. On both occasions the cottonmouth returned to the water snake and continued trying to swallow it. When the cottonmouth released the water snake for the third time, it retreated to the water. However, as we left the area, the cottonmouth was swim-

ming back toward the water snake, presumably to try again.

Cottonmouths will eat dead fish and birds in the wild (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex. SSAR, Oxford, Ohio; Wharton 1966. Copeia 1966:149-161), but this is the first record we know of in which one attempted to consume a dead reptile in a natural situation.

We thank D. E. Scott, R. U. Fischer, and M. S. Mills for comments on the manuscript. Research related to this observation was supported by Contract DE-AC09-76SR00-819 between the University of Georgia and the U.S. Department of Energy.

Submitted by **HOWARD J. BERNA** and **J. WHITFIELD GIBBONS,** Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA.

BOTHRIECHIS NIGROVIRIDIS (Speckled Palm Viper). **MAXIMUM SIZE.** On 27 April 1988 two female *Bothriechis nigroviridis* arrived at the Dallas Zoo on breeding loan from the Central Florida Zoological Park. Both animals were acquired on 13 November 1983 from a local collector from Alto La Palma, San Jose Province, Costa Rica. Both were exceptionally large. In-house identification numbers were assigned to these animals. Female #2 was 721 mm SVL and 892 mm TL while female #3 was 783 mm SVL and 937 mm TL. Referring to this species, Campbell and Lamar (1989. The Venomous Reptiles of Latin America, Comstock Publ. Assoc., Ithaca, New York, 425 pp.) stated: "Although it may exceed 800 mm in total length, it is more commonly less than than 600 mm." Female #3 died on 18 February 1991 and was deposited in the vertebrate collection of the Florida Museum of Natural History (#UF80252).

Submitted by **STEPHEN H. HAMMACK**, Department of Herpetology, Forth Worth Zoological Park, 2727 Zoological Park Drive, Fort Worth, Texas 76110, USA, and **FRED ANTONIO**, Department of Herpetology, Central Florida Zoological Park, P.O. Box 309, Lake Monroe, Florida 32747, USA.

CLELIA CLELIA (Mussurana). **FEEDING BEHAVIOR.** *Clelia clelia* is a large colubrid (TL = 2 m) widely distributed in South America. This species is primarily ophiophagus, but it also captures lizards and small rodents (Cunha and Nascimento 1978. Publ. Avuls. Mus. Paraense E. Goeldi 10:1-218). On 25 May 1989, at Engenho Agua Azul, Timbaúba, Pernambuco, northeastern Brazil (07° 31'S, 35° 19'W), we observed an adult *C. clelia* attacking a nest of the brown four-eyed opossum (*Metachirus nudicaudatus*) during the day. The nest was located 1 m above the ground in a small bush, and housed two juvenile opossums (228 mm TL, 35 g). One juvenile had been swallowed by the snake, and the other was being killed by constriction. We recorded no aggressive reaction by the adult female opossum, but we did observe it walking around the snake chattering its teeth. Predation of marsupials by South American snakes may be more common than believed. Opossums of the genus *Marmosa* have been recorded as prey of boids, probably *Epicrates cenchria* (Ribeiro 1936. Rev. Mus. Paul. 20:245-427), and we have previously observed predation on the woolly mouse opossum (*Marmosa cinerea*) by *Spilotes pullatus*.

Amphibians and Reptiles of the West Indies

Descriptions, Distributions, and Natural History

Albert Schwartz **Robert W. Henderson**

"A monumental volume."—*Bookman's Weekly*

"A definitive synopsis of West Indian herpetofauna providing the novice or experienced biologist with a concise introduction into the natural history and natural history literature of every species of amphibian and reptile. . . . Biologists doing fieldwork in the West Indies will find themselves constantly referring to this synopsis whether they are in the field or at home in their research lab."
—George R. Zug, curator, Division of Amphibians and Reptiles, National Museum of Natural History, Smithsonian Institution

Provides a detailed account of each of almost 600 reptiles and amphibian species including description, holotype, source of illustrations, and range map. A section on natural history summarizes what is known about the habitat, microhabitat, economic bearing, food habits, and reproduction of each animal, including variations from island to island.

HETERODON NASICUS KENNERLYI (Mexican Hognose Snake). **OOPHAGY.** In August 1986 I received an amelanistic female *Heterodon nasicus kennerlyi* from David Lazcano, Jr. of the Museo de Historia Natural, Universidad Autonoma de Nuevo Leon. The coloration of this specimen had been reported previously by Lazcano (1988. Herpetol. Rev. 19(2):36). The animal has been bred four times. In 1987, seven offspring were produced and in 1988, four offspring were produced. In both of these breeding seasons the amelanistic female was bred to a normal-colored, homozygous male. During the breeding seasons of 1989 and 1990, the amelanistic female was bred to heterozygous males that were her own progeny from the 1987 breeding season. On 15 July 1989 a nest box was placed in with the female, after it was apparent that she was gravid. On 16 July 1989 she shed and nine eggs could be felt be gentle palpation. On 25 July 1989 at 0630 h, three eggs were deposited in the nest box. The female was left alone until 2100 h, when only one egg was found remaining in the next box. Based upon a mid-body enlargement, it was apparent that the female had consumed two eggs. On 30 July she passed a very yolky stool containing remnants of eggshells.

A similar incident occurred in 1990. On 12 July 1990 the female shed and a nest box was placed in her cage. On 14 July 1990, six eggs could again be felt by gentle palpation. On 30 July 1990 at ca. 0700 h, one egg was found in the nest box. The female was again left alone until later that night. At ca. 1900 h, only two eggs could be found and once again the female was large at mid-body. On 4 August 1990 the female passed a yolky stool with remnants of eggshells. Egg-eating behavior was not observed during the 1987 or 1988 breeding seasons.

Submitted by **STEPHEN H. HAMMACK**, Department of Herpetology, Forth Worth Zoological Park, 2727 Zoological Park Drive, Fort Worth, Texas 76110, USA.

LEPTOPHIS AHAETULLA (Parrot Snake). **FEEDING BEHAVIOR.** The diet of *Leptophis ahaetulla* typically is composed of small frogs and geckos captured on the ground or in low vegetation (Cunha and Nascimento 1978. Publ. Avuls. Mus. Paraense E. Goeldi 10:1-218; Vanzolini et al. 1980. Répteis das Caatingas, Rio de Janeiro, 161 pp.). In the highland forests of Pedra Branca, Murici, Alagoas, northeastern Brazil (09° 15'S, 35° 50'W), this species forages in the canopy 20 m above the ground. We observed an adult *L. ahaetulla* swallowing a feathered chick of the flame-crested tanager (*Tachyphonus cristatus*) during the day. *L. ahaetulla* is recognized by birds as a potential predator, and is pursued by mixed flocks of passerines. Specimens were deposited in the collection of Museu Nacional/UFRJ.

Submitted by **DANTE MARTINS TEIXEIRA** and **MARCOVAN PORTO,** Departamento de Vertebrados, Museu Nacional/UFRJ, Rio de Janeiro 20.942 Brazil.

TROPIDOPHIS HAETIANUS (NCN). **LOCOMOTION.** On 7 June 1991 two adult *Tropidophis haetianus* were collected at the edge of a stream near Canoa at the junction of HW 44 and the road to Pto. Alejandro, and on 12 and 14 June 1991 two juvenile *T. haetianus* were collected 5.6 km W of HW 44 on the Sta. Helena road, this junction is 4.1 km south of the Hotel Guarocuya in Barahona; both sites are in the Provincia de Barahona, República Dominicana. During a photography session involving the first-captured juvenile (SVL = 163 mm), an effort was made by the snake to escape by sidewinding. When given the opportunity, the second juvenile (SVL = 241 mm) behaved similarly, as did the adult male (SVL = 520 mm) captured earlier. All three animals used the same pattern of locomotion on a variety of substrates, including a tile floor, carpet, a tightly stretched sheet, poured concrete, grass, and sand. The adult female was gravid and resisted all attempts to induce movement by refusing to uncoil from a defensive ball. The sidewinding pattern (Fig. 1) resembled that of *Crotalus cerastes* and left a similar track in sand. It differed, however, in that the direction of movement was more parallel to the long body axis than in sidewinding rattlesnakes. Individuals "looped" their bodies to either the left or right as they moved in a forward direction.

Specimens were deposited in the Bobby Witcher Memorial Collection (BWMC 04481, 04587, 04606), Avila College. The adult female is being held alive at Avila College.

Michael C. Schreiber made the videotape from which the illustration was produced. We also wish to thank Sixto Incháustegui, who provided assistance in the Dominican Republic. José A. Ottenwalder of the Parque Zoológico Nacional facilitated opportunities for field work. Permits were provided by Emílio A. Bautista M., Director, Departamento de Vida Silvestre, República Dominicana.

AMBYSTOMA JEFFERSONIANUM (Jefferson Salamander). USA: ILLINOIS: Clark Co: Lincoln Trail State Recreation Area. 2 March 1991. C. A. Phillips. Verified by Thomas Uzzell. UIMNH 95674. One juvenile raised from a larva dipnetted from a small pond. First record for species in Illinois (Smith 1961. Nat. His. Surv. Bull. 28(1):1–298) and range extension ca. 15 km west of record for Vigo County, Indiana (Hay, 1887. Annu. Rep. Indiana St. Board Agr.: 201–227).

Submitted by **CHRISTOPHER A. PHILLIPS**, Department of Ecology, Ethology and Evolution, University of Illinois, Urbana, Illinois 61801, USA. ●

AMBYSTOMA MACULATUM (Spotted Salamander) USA: ILLINOIS: Clark Co: Lincoln Trail State Recreation Area. 2 March 1991. C. A. Phillips. Verified by Thomas Uzzell. UIMNH 95666. New county record (Smith 1961. Nat. Hist. Surv. Bull. 28(1):1–298).

Submitted by **CHRISTOPHER A. PHILLIPS**, Department of Ecology, Ethology and Evolution, University of Illinois, Urbana, Illinois 61801, USA. ●

AMBYSTOMA MACULATUM (Spotted Salamander). USA: NORTH CAROLINA: Hyde Co: 4.5 km SSE Sladesville. 29 January 1990. NCSM 30435 (DOR adult); 3.5, 3.9, & 4.0 km NNE Scranton. 9 January 1991. NCSM 31197–99 (DOR adults). All collected by R. W. Gaul, Jr. Verified by W. M. Palmer. New county records; only one previous record from the lower coastal plain of North Carolina; extends range ca. 17 km SSE & 9 km ESE of nearest record in Beaufort County (NCSM files).

Submitted by **JEFFERY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 27647, Raleigh North Carolina 27611, USA, and **R. W. GAUL, JR.**, Route 1, Bath, North Carolina 27808, USA. ●

DESMOGNATHUS OCHROPHAEUS (Mountain Dusky Salamander). USA: TENNESSEE: Coffee Co: Small spring-fed creek off Lyndell Bell Road, 2.9 km S Blantons Chapel Road. 20 March 1991. B. T. Miller. Verified by Wayne Van Devender. Middle Tennessee State University (MTSU 35C, 36C). New county record; extends the distribution into the Eastern Highland Rim of middle Tennessee, ca. 45 km W of populations in the Cumberland Plateau and 55 km north of the presumably disjunct populations in the Cumberland of northern Alabama (Redmond, MS. A biogeographic study of amphibians in Tennessee, Unpubl. Doctoral Diss. subm. 1985, Univ. Tennessee, Knoxville. 290 pp.; Tilley 1973. *Desmognathus ochrophaeus*. Cat. American Amph. Rept. 129.1–129.4).

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA. ●

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: ILLINOIS: Vermillion Co: Middle Fork State Fish and Wildlife Area. 29 April 1991. C. A. Phillips. Verified by Thomas Uzzell UIM 95645. One adult. New county record (Smith 1961. Nat. Hist. Surv. Bull. 28(1):1–298) and sixth isolated population reported for state since 1961 (Michael Morris, unpubl. data).

Submitted by **CHRISTOPHER A. PHILLIPS**, Department of Ecology, Ethology and Evolution, University of Illinois, Urbana, Illinois 61801, USA. ●

ANURA

BUFO AMERICANUS (American Toad). USA: LOUISIANA: East Baton Rouge Parish: ca. 5 km N Greenwell Springs. 11 May 1990. J. Wilkinson. Verified by David A. Good. LSUMZ 49497. Second parish record, extends range about 30 km southwest of nearest record.

Submitted by **J. SEAN DOODY** and **JEFFERY A. WILKERSON**, Museum of Natural Science, 119 Foster Hall, Louisiana State University, Baton Rouge, Louisiana 70803, USA. ●

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). USA: ARKANSAS: Pope Co: NE 1/4, NE 1/4, SW 1/4 Sec. 14, T7N, R20W. 6 June 1990. Jim Price & Don Price. Verified by Glyn Turnipseed. KU 216104. County record.

ANOLIS CAROLINENSIS (Green Anole). USA: TEXAS: Goliad Co: grounds of Goliad County Courthouse. 28 April 1991. Michael B. Keck & Fred L. Rainwater. Verified by J. R. Mendelson. UTACV R 30069–70. County record (Dixon 1987. Amphibians and Reptiles of Texas. Texas A&M University Press. College Station, Texas. 434 pp.)

Submitted by **MICHAEL B. KECK**, Department of Biology, University of Texas at Arlington, Texas 76091, USA, and **PAUL D. KLAWINSKI**, Department of Biology, Stephen F. Austin State University, Nacogdoches, Texas 75962, USA. ●

ANOLIS CHLOROCYANUS (Hispaniolan Green Anole). DOMINICAN REPUBLIC: BARAHONA: Barahona Central. 8 March 1988. Bobby Witcher Memorial Collection (BWMC) 3733, Avila College, Kansas City, Missouri; Barahona, Hotel Guarocuya. 22 May 1989. BWMC 4022; 9.5 km N Barahona, cane fields. 4 March 1990. BWMC 04206–04211; Barahona Central. 15 June 1991. BWMC 4659. R. Powell, J. S. Parmerlee, Jr., D. D. Smith, A. J. Lathrop, and others. Verified by Adrian Nieto. These specimens extend the known range along mesic coastal lowlands south through Barahona, and represent the southeasternmost records of this species, which is widely distributed throughout the "north" island of Hispaniola (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville). The Hotel Guarocuya, on the southern edge of the city of Barahona, apparently represents the current limit of the species' distribution.

lege, Kansas City, Missouri 64145, USA, **DONALD D. SMITH**, Division of Allergy & Rheumatism, University of Kansas Medical Center, Kansas City, Kansas 66103, USA, & **AMY J. LATHROP**, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045, USA. ●

CROTAPHYTUS INSULARIS VESTIGIUM (Baja Black-collared Lizard). MÉXICO: BAJA CALIFORNIA DEL SUR: 27.7 km (by road) SE San José de Comondú. 9 July 1991. J. A. McGuire & L. L. Grismer. Verified by Richard Etheridge. Los Angeles County Natural History Museum Photograph Collection (LACM PC 1207). Extends known distribution ca. 29 km to southeast. This locality represents the southernmost volcanic mesa of the Magdalena region accessible by road. Previously, it was thought that the distribution of this subspecies terminated ca. 4.1 km (by road) north of San José de Comondú (Smith and Holland 1971. J. Herpetol. 5(1–2):56–59), despite the continuation of suitable habitat to the south. It is likely that *C. i. vestigium* does not inhabit the southern Sierra de la Giganta in the vicinity of San Javier, and that its southernmost distribution is bounded by the volcanic mesas that terminate south of San José de Comondú. Contrary to Stebbins (1985. A Field Guide to Western Reptiles and Amphibians, Houghton Mifflin Co., Boston, Massachusetts. 336 pp.), *C. i. vestigium* is not known from the vicinity of Loreto, which is located on the east side of the Sierra de la Giganta, and has not been collected south of the turnoff to La Purisima (ca. 65 km north of Loreto) on the east side of the peninsular ranges.

Submitted by **JIMMY A. MCGUIRE**, Department of Biology, San Diego State University, San Diego, California 92182–0057, USA. ●

EUMECES OBSOLETUS (Great Plains Skink). USA: MISSOURI: Barry Co: 1.8 mi E Rt. M on Rt. E. 16 August 1991. Kevin R. Toal & Randy Reiserer. KU 218527. Verified by Joseph T. Collins. New county record that extends the distribution southeast from the nearest previously reported Missouri record south of Joplin, Newton County (Powell et al. 1990. Missouri Herp. Assn. Newsl. 3:4–8), and a slight eastern extension of the known range of the species in southwestern Missouri as shown by Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

CORRECTION

In a previous range extension of *Epipedobates trivittatus* to Venezuela (Gorzula and Balbas 1991. Herpetol. Rev. 22(3):102), the inclusion of Maria Jose Praderio as the identification verifier is in error. The identification of these specimens has not been verified. ●

BOOK REVIEWS

Snakes of Iran, by Mahmoud Latifi. Translated by Sepideh Sajadian and edited by Alan Leviton and George Zug. 1991. Society for the Study of Amphibians and Reptiles, viii + 159 pp. Hardcover. $22 U.S.

The interesting snake fauna of the region west of the Indian subcontinent and south of the USSR is poorly known apart from local studies by Gasparetti in the Arabian peninsula and Mendelssohn and others in Israel. As Director of the Department of Herpetology and Antivenom Studies of Razi Institute, Iran's principal laboratory for serum and vaccine production, Dr. Latifi has had a unique opportunity to study the Iranian snake fauna. In 1985 this led to his publication of "Snakes of Iran," written in Farsi and intended primarily for distribution in Iran. The book is written for the non-specialist Iranian reader and must be judged accordingly, although the editors and translator have modified it for a broader English-speaking audience.

The book is divided into two major sections. The first deals in a general manner with the anatomy and biology of snakes, their distribution and ecology in Iran, venomous snakes, and the symptoms and treatment of snakebite. Most of this is material well known to the average herpetologist, although some has a distinctly local flavor. Recommendations for management of snakebite are generally sound although differing in some details from the protocol usually advocated in the U.S. Throughout this section, the snakes usually are referred to by their colloquial names, so the reader must remember that the Gafari snake is *Echis carinatus* and the ladle snake *Naja n. oxiana*. Literal translation of some Farsi snake names is unfortunate. "Blind snake" to most American herpetologists means a *Leptotyphlops* or *Typhlops* but in Iran it refers to the sand boas, *Eryx*; "wolf snake" is applied to *Lycodon striatus* and *Coronella austriaca*, two quite different serpents.

The second section of the book contains a list of the snakes of Iran, their general distribution, and Iranian distribution by provinces. This is followed by a key to the Iranian snakes. Most of this section consists of species accounts which include description, size, diet, reproduction, and habitat. There is a good general bibliography and a list of some Iranian references not widely available. The list of Iranian snakes reflects best current knowledge, although additional sea snakes such as *Astrotia* and *Praescutata* almost certainly occur along the Iranian coast. The distributional information is valuable; there are topographic and political maps of Iran as well as a small distribution map for each species. The latter often indicate species needing study; for example, *Coluber r. rhodorachis* and *C. r. ladacensis* both are shown as having nation-wide distributions.

I had trouble with the key, for early on I had to decide whether head scales of *Eryx* are smaller than those of most viperids. The species accounts of habits and habitat often are brief, overly generalized, or incomplete, but it must be remembered that many of these snakes are poorly known, and this book provides the only available information about them. The book closes with a supplementary bibliography compiled by the editors and an update of taxonomic nomenclature since the original publication in 1985.

Each species is illustrated by a color drawing, sometimes of the entire animal, in other cases only of the head and forebody. The body conformation depicted sometimes is misleading. *Vipera lebetina* seems a bit too slender for the species as I know it, while *Boiga trigonata* is too stout. The configuration of *Hydrophis cyanocinctus* is poor unless modeled on a very young animal; the head of the adult is smaller and the neck much more slender and elongate. Pattern is well depicted, but the colors are poorly reproduced and appear mostly as shades of gray or brown. I know the colors of many of these snakes as much richer than shown here.

Any herpetologist interested in snakes of the Middle East or in the world snake fauna should have this book, and I recommend it to those interested in the zoogeography of Eurasian reptiles. Physicians or other medical personnel anticipating a tour of duty, military or otherwise, in the Middle East will find useful information on snakes and snakebite. Dr. Latifi has written an authoritative book for a wide audience; one hopes it will be followed by others.

The Frogs of Zimbabwe, by Angelo J. L. Lambiris. Monografia X, Museo Regionale di Scienze Naturali, Torino, Italy, 1989. 247 pp., 24 color plates.70,000 lira, approx. US $58.

Although the frog fauna of Africa pales beside that of South America, students of African frogs have a considerable advantage, a tradition of making these animals and their habits more accessible to specialists and the general public alike. South Africa had its fauna treated technically by Poynton (1964) and subsequently by less technical but more information dense accounts by Wager (1965, 1986) and Passmore and Carruthers (1979). Poynton and Broadley extended Poynton's treatment to cover Zimbabwe and adjacent countries in a series of four technical accounts (1985a, b, 1987, 1988) and laid the groundwork for Lambiris' account of Zimbabwe frogs.

This is neither a technical monograph nor a field guide but somewhere in between. All illustrations are documented

Announcing:

Biology of the Pitvipers

Edited by Jonathan A. Campbell & Edmund D. Brodie, Jr.

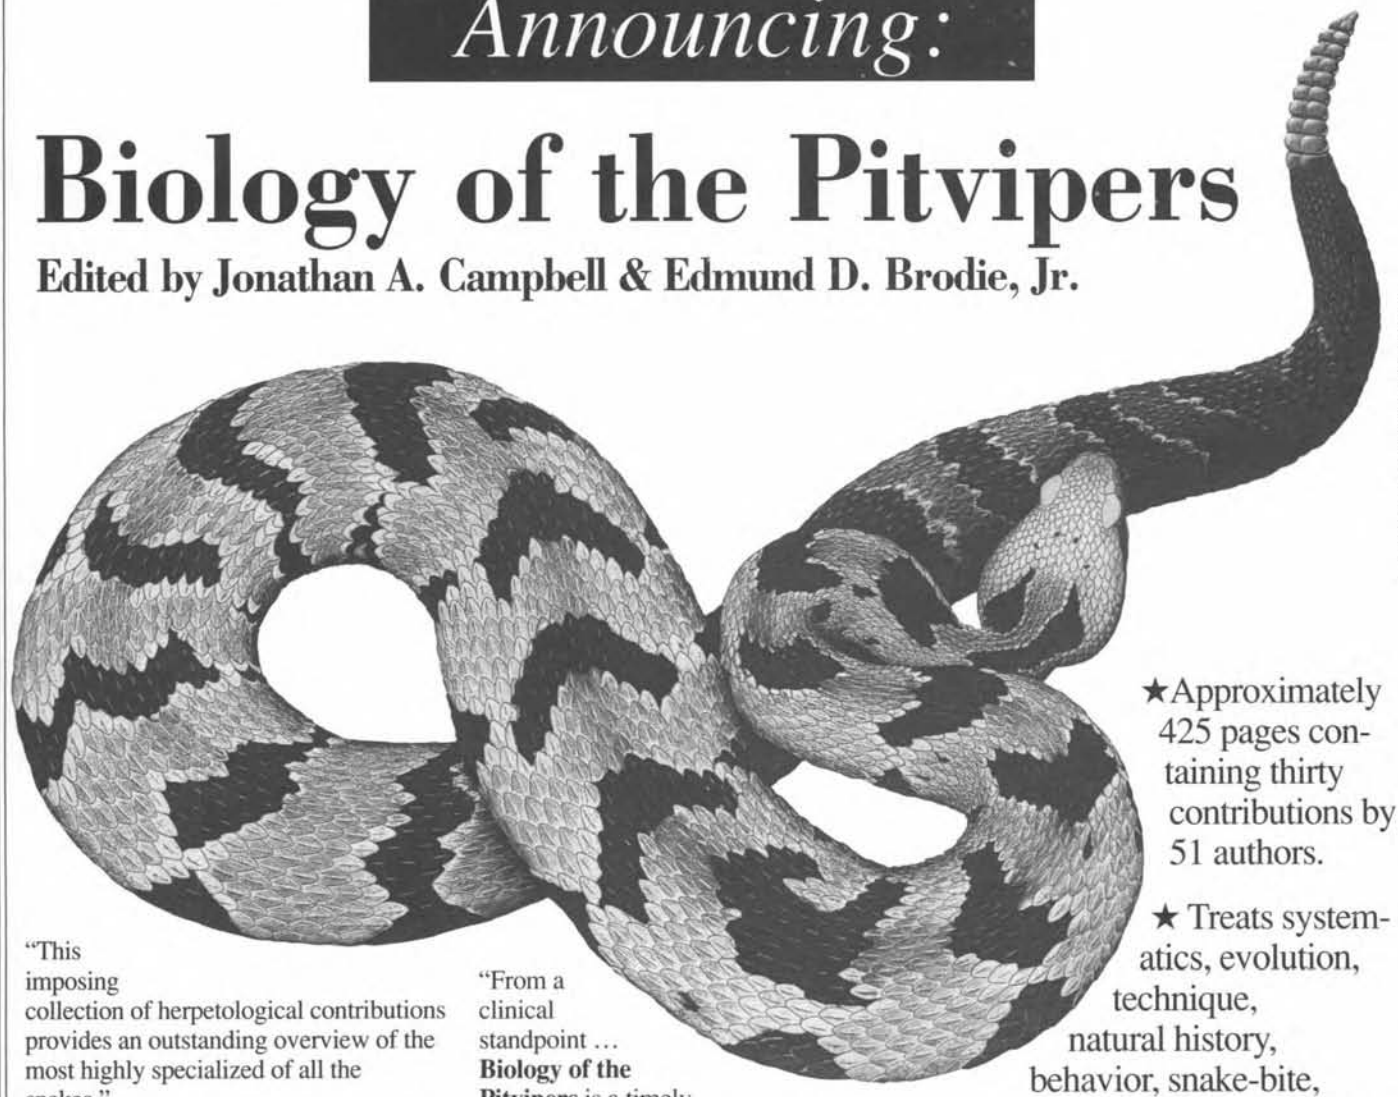

Illustration © 1991 William B. Montgomery

"This imposing collection of herpetological contributions provides an outstanding overview of the most highly specialized of all the snakes."

Roger Conant - Adj. Professor, The University of New Mexico

"This volume is a good investment for serious students of viper evolution and ecology. The editors have brought together a number of timely, solid contributions that succeed admirably in providing both a good introduction, summaries of previous work, and new data and ideas. Recent years have brought us a number of other symposium volumes, but few have achieved this general level of scholarship."

Darrel R. Frost - Ass't. Curator of Herpetology, American Museum of Natural History

"From a clinical standpoint … **Biology of the Pitvipers** is a timely addition to the American snakebite literature… The sequelae for pitviper poisoning in the United States by RC Dart et al fills an important gap in the literature. It documents for the first time the long range effects of pitviper bites in a careful, systematic and scientific fashion. The entertaining and readable style in which this account is written is an added bonus. [David Hardy's] comprehensive evaluation of the Extractor® suction device and Stun Gun® electroshock are the most in-depth and thorough reviews to date of these controversial maneuvers."

George Watt M.D., DTM&H - Chief, Department of Medicine, AFRIMS

★Approximately 425 pages containing thirty contributions by 51 authors.

★ Treats systematics, evolution, technique, natural history, behavior, snake-bite, maintenance and conservation.

★ 121 color photos, 100 black & white photos.

★ Case bound, with dust jacket.

The cover illustration of a Canebrake Rattlesnake, *Crotulus horridus*, by artist William B. Montgomery, was commissioned especially for **Biology of the Pitvipers**. It is a limited edition etching, hand printed on acid-free archival paper, signed and numbered by the artist. Each impression is individually hand colored by the artist using light-fast watercolors.The 16" x 22" prints will be sold for $100.00 (includes shipping). A special discount of 25% off will be available for a limited time. For more information contact SELVA.

Due for publication: January 1992 • Approximate cost: U.S. $75.00 • ISBN 0-9630537-0-1

(of particular specimens whose catalogue numbers and locality data are provided in the legends). The distribution maps do not include dots but rather report distributions by shaded-in areas on the maps. No locality data are provided aside from data in legends and the occasional taxon known from single localities. Call information is reported using everyday language/description rather than using sonograms or quantitative descriptions.

Following introductory materials (in which many drawings are provided showing structures mentioned in the keys and descriptions), mostly about frogs, we are provided the systematic accounts arranged in a traditional "phylogenetic order."

The Zimbabwe fauna consists of pipids (3 taxa), bufonids (9 taxa), microhylids (4 taxa), hemisotids (2 taxa), hyperoliids (19 taxa), rhacophorids (1 taxon), and 29 taxa assigned to the Ranidae (subfamilies Arthroleptinae, Phrynobatrachinae, and Raninae). The familial arrangement and some generic assignments differ from those used by Frost (1985). Each taxon is provided with a brief diagnosis (distinguishing it from other Zimbabwean frogs), description, habitat and behavior, call and call sites, breeding and development, a statement of the distribution of the species or subspecies, and a note regarding similar species (those with which it might be confused). For every taxon, outline drawings of the hand and foot, tadpole (in lateral view), and tadpole mouthparts (when known) are provided. With the limited materials available to me, I found Lambiris' keys and descriptions easy to use and accurate.

Paintings (in color) are provided for 64 of the 67 taxa, using a style which reminds me of many ornithological field guides (the animals are in three quarter view and duplicate outlines are provided to report variation in coloration or color pattern). Only four species are shown in as few as two paintings (ventral view and three quarter view) and *Hyperolius marmoratus broadleyi* is shown in 13 views. Most species are shown in three views (two three quarter and one ventral). Colors compare favorably with published color photographs. All illustrations in the text are the work of the author.

Lambiris' book invites comparison with those of Passmore and Carruthers (1979) and Stewart (1967). All three works deal with comparable faunas except that South Africa has heleophrynids (3), a few more bufonids (13), and several more breviciptine microhylids (11) than do the other regions. Passmore and Carruthers (1979) is more an identification guide than are the other two volumes and it has superb color photographs and many black and white photographs focused on structural features of the organisms. By way of contrast, Stewart's (1967) book has few color photographs and many ink drawings of frogs. Stewart's book provides a great deal of descriptive detail about the frogs. Lambiris' book has a tadpole focus, recalling Wager (1965) for South Africa. The three books treat many of the same taxa but each addresses some endemic taxa. Because they treat the faunas in different ways, each provides an important window to the African fauna.

Lambiris' treatments will be most useful to those with firsthand experience in that part of the world. Reproductive seasons are expressed relative to the onset of rainy seasons without a calender reference. I was frustrated by his expressing the size of animals in terms of the largest individual found (or measured). Frogs reach sexual maturity at some smaller size but fortunately, Stewart (1967) provides these data for Malawi taxa. Although size is indicated in all line drawings, I would have appreciated information on the sizes of tadpoles as well as the size at which various species transform.

Information for Contributors

The following statement-of-purpose appeared in the Introduction to the first issue of ***Herpetological Review*** in 1967 (Corson Hirschfeld, Editor):

"*Herpetological Review* incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of individuals, institutions, literature and other components of the field. Perhaps equally important, the *Review* will provide a means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. ***HR*** publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, description of new taxa, or taxonomic revisions are not published in ***HR***; such material should be submitted to the ***Journal of Herpetology*** (see inside front cover for address).

Manuscripts should be typewritten, double spaced, on 21.5 X 28 cm (8.5 x 11 inch) white paper. Authors are requested to submit four copies of feature article manuscripts. We strongly encourage submissions on a Macintosh disk in Microsoft Word 4.0, although other word processing programs in a Macintosh format (e.g, WordPerfect, MacWrite) are acceptable, as are DOS-formatted disks. Submission by disk will greatly facilitate the review and editing process and reduce the time from submission to publication. Submission on disk must be accompanied by hard copy. Refer to a recent issue of ***HR*** for style and format information. More detailed instructions for submission to Geographic Distribution, Life History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under the appropriate heading.

Submissions for Life History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislative Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Feature articles, newsnotes, and other material should be sent to the Editor. Books for review should be sent directly to the Book Review Section Editor (name and address on inside front cover).

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion. RWH

SOCIETY FOR THE STUDY OF AMPHIBANS AND REPTILES

NEW PRICE for the

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The catalogue consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere.

COMPLETE SET: NUMBERS 1 - 505 ..... $190.00

IINDEX TO ACCOUNTS 1 - 400: Cross-referenced, 64 pages $5.00

SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.) $5.00

IMPRINTED POST BINDER: (note - two binders are needed for the 505 accounts) $25.00

INCOMPLETE SET: NUMBERS 1-190 ..... $60.00
91 - 410 ..... $70.00
411 - 505 ..... $60.00

Make checks payable to: "SSAR" and mail to:

Society For The Study Of Amphibians And Reptiles

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (4 issues annually), **Herpetological Review** (4 issues annually), and occasional issues of **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1991

Student member	$25.00*	Sustaining member	$50.00*
Regular member	$35.00*	Contributing member	$75.00*
Institutional subscription	$60.00*	Life member (see below)	$600.00*

*** Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00 Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Life memberships may be paid in 3 consecutive payments. Subscriptions to Herpetological Review only are available for $12.00 annually. Subscriptions outside of the US require a surcharge of $8.00 for air delivery if airmail is desired. Subscribers to HR only are not members of the Society. Catalogue of American Amphibians and Reptiles: subscription is $15 annually ($3.00 air delivery surcharge if airmail is desired.). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

HERPETOLOGICAL REVIEW

Volume 22 September 1991 Number 3

SSAR BUSINESS

SSAR IS LOOKING FOR A FEW GOOD SITES

The SSAR Board and the Joint Local Meetings Committee (shared with the Herpetologists' League) are looking for persons and institutions who are interested in hosting an SSAR Annual Meeting. Although the committee is currently involved in discussions with several institutions, we do not now have any commitments beyond the 1992 meeting in El Paso, Texas.

Although SSAR meetings are no longer small (New Orleans drew 500 in 1990), the reward to host individuals and institutions goes beyond service to the society. A meeting is a good way to gain visibility for a program, and thus to attract future students (many attending herpetologists to take note of facilities, programs, and projects). Whereas ultimate responsibility falls on one or two persons, assistance in planning is available from the society and most institutions, and resources outside the institution include local zoos and regional societies.

Anyone interested in hosting such a meeting should contact the Secretary, J. Eric Juterbock (address on inside back cover). ●

SSAR GRANTS-IN-HERPETOLOGY

Proposals are now being accepted for the 1992 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR, with the exception of those applying in the REGIONAL HERPETOLOGICAL SOCIETY category. Applicants are limited to submission of one proposal in one category per year. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Grant proposals will be considered in the following categories:

1. REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address educational projects, speakers' fees, regional research, defrayment of one-time-only costs, or other purposes that would strengthen regional societies. Proposals may be submitted by regional herpetological societies or by individual members and must be accompanied by a letter of support from the current president of the regional society.

2. HERPETOLOGICAL RESEARCH OR EDUCATION IN ZOOS. Proposals may address any herpetological endeavor conducted in zoos, such as improvement of displays, interpretive graphics, husbandry, or behavioral research. A letter of support from the herpetological curator or the director of the sponsoring zoo must accompany the proposal.

3. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species. Proposals must be from individuals only and must be accompanied by a letter of support from another member of the SSAR.

4. FIELD WORK. Proposals may address support for travel to ecological study sites or for survey collections. Proposals normally submitted in the CONSERVATION or GRADUATE STUDENT RESEARCH categories should be submitted here if travel or field station support is sought. Proposals must be from individuals only and accompanied by a letter of support from another member of the SSAR.

5. GRADUATE STUDENT RESEARCH IN HERPETOLOGY. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only. Applications must be accompanied by a letter of support from the student's major advisor or committee chairperson.

Each proposal must include the following: (A) BACKGROUND AND OBJECTIVES of the proposed project. (B) METHODS of carrying out the project. (C) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). (D) BRIEF RESUMÉ of the applicant or project coordinator. (E) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages, excluding resumé and budget.

Applicants must designate to which of the five categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than 31 December 1991. Failure to meet the guidelines may result in elimination of a proposal from consideration. The awards will be announced by 1 April 1992. Successful applicants will be expected to submit a written report of the results of this support within a reasonable amount of time after the project year is completed. They are also encouraged to submit the results of research projects for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to:

A. Dale Belcher, Chair (505) 843-7413
SSAR Grants-in-Herpetology
Rio Grande Zoo
903 Tenth St. SW
Albuquerque, New Mexico 87102-4098,
USA

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number and/or size of awards. Your tax-deductible contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program. ●

PUBLICATION DELAY

MIDDLE EAST BOOK

The SSAR book, "Herpetofauna of Iraq, Kuwait, and the Arabian (Persian) Gulf," due for publication this summer, will be delayed until late in 1991. Despite our high hopes to produce this book in less than one year after the invasion of Kuwait, the work has been more time-consuming than expected. Nevertheless, as one positive result of the delay, the number of color plates has been doubled, from 16 to 32, and about 80% of the species will now be in full color (210 photos).

Copies of the book can be ordered for $28 clothbound and postpaid in USA. Send orders to Dr. Robert Aldridge, SSAR Publications Secretary, Department of Biology, St. Louis University, St. Louis, Missouri 63103, USA. Further details in Herpetological Review, 21(4): 72, December 1990.

We regret this delay and appreciate the continued patience of the subscribers. — The Editor.

ANNUAL REPORT (1991) OF THE GRANTS-IN-HERPETOLOGY COMMITTEE

Committee: Dale Belcher, Rio Grande Zoo; Maureen Donnelly, AMNH; Tom Fritts, USNM; D. Frost (Chair), AMNH; Jerry Johnson, El Paso Community College; Michael Plummer, Harding University; Dawn Wilson, University of South Florida.

Five awards were made this year of $300 each. These are:

1. Zoo Research or Education (Cecelia Chang Award)—John Steven Conners, Birmingham Zoo, 2630 Cahaba Road, Birmingham, Alabama 35223, USA. Title: An interactive exhibit to interpret reptile thermoregulation at the Birmingham Zoo.

2. Regional Society Programs or Projects—Tucson Herpetological Society, Speaker's Bureau (Travis La Duc and Roger Repp). THS Speaker's Bureau, PO Box 31531, Tucson, Arizona 85751-1531, USA. Project proposal: Request for funds to develop a slide library.

3. Conservation—Glenn Johnson, 224 Illick Hall, SUNY Coll. Environ. Sci. & For., Syracuse, New York 13210, USA. Title of proposal: Conservation biology and spatiotemporal ecology of the eastern massasauga *(Sistrurus catenatus catenatus)*.

4. Field Work—Dwight P. Lawson, Department of Biology, UTA Box 19498, University of Texas at Arlington, Arlington, Texas 76019, USA. Title of proposal: Systematic revision of the *Porthidium nummifer* complex.

5. Graduate Student Research—Karen R. Lips, Department of Biology, University of Miami, PO Box 249118, Coral Gables, Florida 33124-9118, USA. Title of proposal: Metamorphic strategies in a tropical stream-breeding frog *(Hyla lancasteri)*. ●

NEWSNOTES

IUCN SPECIES SURVIVAL COMMISSION ESTABLISHES DECLINING AMPHIBIAN POPULATIONS PROGRAM

During the past several years there has been increasing public concern for the habitat destruction and species extinctions being measured on a global scale. One facet of these universal phenomena is exemplified by reports from biologists of a widespread decline in amphibian populations. Although the amphibian declines are not consistently noted at all locations, nor among all species, their magnitude is undeniable. The significance of these reports is accentuated by certain characteristics of amphibians (e.g. biphasic life cycle, permeable skin, etc.) that provoke a sensitivity of response to varying environmental conditions. Consequently, many species are considered to be early indicators of potentially drastic changes in ecosystems.

Following an international symposium convened by Dr. John W. Wright (Los Angeles County Museum of Natural History) at the annual joint meetings of the Society for the Study of Amphibians and Reptiles and the Herpetologists' League, a clear consensus emerged as to the world-wide character of the problem and the need for immediate action. In response to this demand the World Conservation Union (IUCN), Species Survival Commission, activated the Declining Amphibian Populations Task Force with David B. Wake (University of California, Berkeley) as Chair. The focus of this program is to provide a global coordinating center for investigators and agencies concerned with documentation and determination of causes of these declines. It will also identify priorities for research on indicator species in critical habitats. An inherent component of these objectives will be the prescription of uniform protocols by which studies of different species and habitats can be compared.

Overseeing the activities of the Task Force will be a Board of Directors, having international representation, that will act within the fabric of the IUCN/SSC. This directorate is responsible for establishing policies, determining priorities and raising funds necessary for the Task Force endeavors. A Coordinating Council will serve as the operational unit for the program. Participants on the Coordinating Council will include researchers, liaison officers of societies and agencies, and others, all of whom serve as communicators for the Task Force. Among its functions will be the collating of all available information, establishing a computerized data base, and setting up a global monitoring program with electronic input and access (these collectively representing what is popularly referred to as the "FROGLOG"). A newsletter will be issued at frequent intervals and distributed to all interested parties.

Managed by a Coordinator with staff support, it is anticipated the Council will be situated in its new headquarters at the Center for Analysis of Environmental change in Corvallis, Oregon by September. James L. Vial, who will be departing from the University of Tulsa, has been appointed as Coordinator.

The Coordinator will also work with the directorate to establish regional Working Groups of independent scientists and technical personnel. The Working Group for Costa Rica/Panama, recently convened

by Jay M. Savage (University of Miami), has been organized with a scientific advisory committee composed of consultants for the project and chaired by the principal investigator.

A project coordinator will oversee the gathering, standardization, and management of all data and is responsible for logistical operations among the several included study sites, each of which is in the charge of a site coordinator. This suggested model should, of course, be modified as suited to the needs of a particular group or project. In addition to field activities, other Working Groups will formulate protocols and facilitate symposia or workshops.

The IUCN/SSC invites persons and organizations interested in the DAP program to correspond with the Task Force Coordinator. In the near future we hope to provide a full-time, full-service operation to all those involved with species conservation and biodiversity. We are immediately concerned with the establishment of a universal communications network and would appreciate any expression of interest on the part of persons who might volunteer service as a communicator. The address, effective September 1, 1991, is:

James L. Vial, Coordinator
DAP Task Force
Species Survival Commission, IUCN
c/o Environmental Research Laboratory
Center for Analysis of Environmental Change
200 SW 35th St.
Corvallis, Oregon 97333, USA ●

JOB ANNOUNCEMENT

Six seasonal technician positions with the Missouri Department of Conservation will be available from 1 February to 15 October 1992. Technicians will construct herp arrays and collect Ozark forest herpetofauna caught in arrays. Work will include marking herpetofauna for possible recapture. This research is part of a larger project to examine the effects of even- and uneven-aged forest management on Ozark forest plant and animal communities. The pay is $4.69/hour for 40 hours per week. Housing, utilities, and vehicles in Ellington, Missouri will be provided. To receive an official application, please send cover letter and resumé to Dr. Rochelle B. Renken, Missouri Department of Conservation, Wildlife Research Center, 1110 South College Avenue, Columbia, Missouri 65201, USA or call (314) 882-9880. Interviews will be conducted by phone or in person. Applications must be received by 1 November 1991. ●

ATTENTION OVERSEAS MEMBERS

Announcements for the 1992 SSAR Meeting in El Paso, Texas will not automatically be mailed to overseas addresses. Overseas members wishing to receive an announcement (including the call for papers) must contact either of the meeting co-chairmen:

Carl S. Lieb
Department of Biological Sciences
The University of Texas at El Paso
El Paso, Texas 79968-0512, USA
(915) 747-5844
or
Jerry D. Johnson
Biology Department
El Paso Community College
P.O. Box 20500
El Paso, Texas 79998-0500, USA
(915) 594-2214

●

INFORMATION REQUEST

The Milwaukee County Zoo is trying to locate living specimens of yellowfoot tortoise *(Geochelone denticulata)* with a carapace length of over 45 cm. Please send any information to:

Richard A. Sajdak
Aquarium/Reptile Curator
Milwaukee County Zoo
10001 W. Bluemound Rd.
Milwaukee, Wisconsin 53226, USA
(414) 771-3040 ●

MEETINGS

CHINA HOSTS ASIAN HERPETOLOGICAL MEETING 1992

The Asiatic Herpetological Society, the Chinese Society for the Study of Amphibians and Reptiles (CSSAR), the China Amphibian, Reptile Specialist Group of Species Survival Committee of I.U.C.N., and the 3rd Sino-Japanese Herpetological Symposium co-sponsored by the Japanese Herpetological Society and CSSAR will hold a joint meeting in Anhui Province, China during July 1992.

This announcement invites members of these societies and other interested individuals to attend the meeting and present papers or posters dealing with the following general topics:

1. The biology and conservation of Asian turtles and tortoises.
2. The biology and conservation of giant salamanders of the genus *Andrias*.
3. The biology and conservation of the Chinese alligator.
4. Herpetological studies of the Himalayas and adjacent regions.
5. Herpetological studies of arid central Asia.
6. Herpetological studies of Asian islands.
7. Tropical Asian herpetological studies.
8. The biology and conservation of Asian amphibians and reptiles in general.
9. Venomous snakes and snake bite treatment in Asia.
10. The captive reproduction of Asian amphibians and reptiles.

The meetings will be held in Huangshan City (formerly Tunxi), Anhui Province, China from 15 July to 20 July 1992. The name of the city, Huangshan, means Mount Yellow, named after the famous mountain near the city. Huangshan Mountain is a United Nations human cultural estate. Anhui Province, located in eastern China, is of great herpetological interest. About 100 species of amphibians and reptiles, including the Chinese alligator and the Chinese giant salamander, occur in the Province. Excursions will be arranged to observe and photograph the Chinese Alligator Research and Reproduction Center. This is the only center in China for conserving this endangered species. There are more than 3000 Chinese alligators at the center, among which over 200 are second generation. Additional excursions will be arranged to visit natural habitats and cultural sites in the Province.

Individuals interested in attending the meeting should write to the following addresses for additional information and to register and submit abstracts:

In China
Dr. Huang Jie-tang
Qimen Institute of Snake Bites
Qimen, Anhui Province, China

In Japan
Dr. Richard Goris
Yokohama City University
School of Medicine
Fukuura 3-9, Kanazawa-ku
Yokohama, 236, Japan

In USSR

Dr. Ilya Darevsky
Zoological Institute
Leningrad, USSR

In USA and all other countries

Dr. Theodore J. Papenfuss
Museum of Vertebrate Zoology
University of California
Berkeley, California 94720, USA

TIMBER RATTLESNAKE SYMPOSIUM: CONSERVATION AND MANAGEMENT

The Massachusetts Audubon Society is sponsoring a one-day symposium on the conservation of the Timber Rattlesnake *(Crotalus horridus)* in the northeast. A petition to the U. S. Fish and Wildlife Service to list the New England, New York, and New Jersey populations as federally endangered will be included in the discussion. The meeting is set for Saturday, December 7 from 9 a.m. to 4 p.m. and will be held at Smith College in Northampton, Massachusetts, USA. Registration is $15 per person. For details, send a SASE to: Rattlesnake Symposium, Massachusetts Audubon Society, South Great Road, Lincoln, Massachusetts 01773 USA.

REGIONAL SOCIETIES

USSR HERPETOLOGICAL SOCIETY

In January 1991, Soviet herpetologists established their first official national herpetological organization, at a meeting held in Pushchino (Moscow region). The society encompasses both professional and amateur herpetologists and is intended to encourage progress in research and conservation. It will also serve as a formal means of communication between Soviet herpetologists and other national groups. Membership is open to all herpetologists. Address the Council Secretary, USSR Herpetological Society: Dr. Tatyana M. Sokolova, Zoological Institute, Academy of Sciences, 199034 Leningrad, USSR.

NEW VETERINARY ORGANIZATION

Veterinarians, veterinary technicians, and veterinary students with an interest in herpetological medicine are invited to join the Association of Amphibian and Reptile Veterinarians (AARV). The AARV is a new organization devoted to improving husbandry and medical care for amphibians and reptiles through education and exchange of ideas among veterinarians and herpetologists. The founders of the AARV are Thomas H. Boyer, D.V.M., of Deer Creek Animal Hospital in Littleton, Colorado and Michelle W. Frahm, D.V.M., of the Gladys Porter Zoo in Brownsville, Texas.

Membership includes subscription to the Association's official publication, *Association of Amphibian and Reptile Veterinarians Newsletter,* the first issue of which is planned for the summer of 1991. The Newsletter will include a forum for exchange of clinical experiences, reviews of current herpetological literature, and original articles on herpetological medicine and captive husbandry.

Membership in the association is limited to veterinarians, veterinary technicians, and veterinary students. Non-veterinarians are welcome to subscribe and participate in the newsletter but are not eligible for membership.

An organizational meeting of the AARV will take place during the annual conference of the Association of Avian Veterinarians in Chicago, Illinois, September 23-28, 1991.

To apply for membership or to subscribe to the newsletter send a letter with your name, address, telephone number, educational degrees, occupation, and primary interests along with a check payable to AARV for $20.00, to: AARV, c/o Michelle Frahm, D.V.M., Gladys Porter Zoo, 500 Ringgold Street, Brownsville, Texas 78520, USA.

ADDRESS CHANGE

The Pro Iguana Verde Foundation has changed its mailing address to:

Apartado 692-1007
San Jose, Costa Rica

Telephone and fax numbers remain the same:

Tel.: (506)31-6756
Fax: (506)32-1950

LEGISLATIVE ALERT

This column is produced by the SSAR Conservation Committee to alert members of the herpetological community to recent and proposed regulatory changes involving amphibians and reptiles. We encourage SSAR members to notify us of any significant changes in state, national, or international conservation laws as they relate to these animals. For further details about any of the following, or to report additional changes, please contact Kurt A. Buhlmann (see inside front cover for address).

The following final and/or proposed listings, regulations, and general information have been announced by governmental regulatory agencies. Pertinent Federal Register (FR) citations are given for U.S. notices.

U.S.A.: *Bufo hemiophrys baxteri* (Wyoming Toad). The federally Endangered Wyoming Toad historically inhabited a 78 km^2 area around Laramie, Wyoming, but now occupies only about 5 km^2. The Nature Conservancy acquired habitat containing the only known population in January 1991. The U.S. Fish and Wildlife Service is preparing a draft environmental assessment for a proposed 1,000 ha national wildlife refuge that would encompass all the toad's known habitat (Endangered Species Tech. Bull. 16(4), 1991).

Massachusetts: On 17 December 1990, the Massachusetts Legislature enacted a strong endangered species protection law. This law will be implemented in January 1992. The most significant component of the new law is the protection provided to habitat for endangered species. For more information contact Henry Woolsey, Coordinator, Massachusetts Division of Natural Heritage and Endangered Species Program.

Florida: As of 1 July 1990, Florida requires all persons who buy or sell live native (Florida) herptiles, to report their transactions four times per year. In addition, persons who buy for resale the carcass, skin, meat, or other body parts of Florida herptiles, except alligators, must obtain a no-cost Amphibian and Reptile Product Dealer's (ARD) Permit and report their transactions. For information and forms contact Florida Game and Freshwater Fish Commission.

Mississippi: New regulations (Public Notice 3071, effective 7 October 1990) regarding commercialization of reptiles and

amphibians. All native reptiles and amphibians in Mississippi are now covered by regulations regarding take. Take for personal use (for species not listed Endangered) requires a small game hunting and fishing license for Mississippi residents ($9) and an all game hunting license for non-residents ($150). Limits on possession are no more than 4 individuals of any one species, and a maximum of 20 reptiles and 40 amphibians. Wild-caught specimens cannot be bought or sold; this includes species which occur in Mississippi but were captured in another state. Captive propagators must be permitted by the state and are subject to inspection at any time. Captive propagators are allowed to take no more than 8 individuals of a reptile species and 16 individuals of an amphibian species from wild populations for breeding stock. For further information contact Robert L. Jones, Nongame Research Section, Mississippi Dept. of Wildlife, Fisheries, and Parks.

FEATURES

FEEDING ECOLOGY OF SPADEFOOTED TOADS (*Scaphiopus couchi* and *Spea multiplicata)* IN WESTERN TEXAS

Although information is available on the feeding ecology and dietary preferences of many species of North American anurans (Inger and Marx 1961), similar information for spadefooted toads is conspicuously lacking (Ruibal et al. 1969; Toft 1985). Bragg (1965) provided some qualitative information on the feeding habits of this group which indicated that they fed largely on ground-dwelling arthropods. In view of the recent interest concerning competition and resource partitioning in reptiles and amphibians (see review by Toft 1985), the present study was conducted in order to provide information on the dietary preferences of the spadefooted toads, *Scaphiopus couchi* and *Spea multiplicata,* from western Texas. No quantitative information is currently available concerning the feeding ecology of these sympatric species.

All animals were collected April through September, 1988. The study area was located within a 20-km radius south to southwest of Marathon, Brewster Co., Texas (the center of the radius was located at 103°13'30"W, 30°11'21"N). The area was bordered by the Pena Colorado Creek to the west and State Highway 385 to the east. Several springs and numerous artificial impoundments provide permanent water. Temporary shallow ponds were found at various locations throughout the area following intermittent rains in April and July. This area is within the Marathon - Alpine Grassland habitat zone (elevation 1333 - 1667 m) as described by Sperry and Warnock (1941). Dominant vegetation consists of grama and chino grass (*Bouteloua* spp.), awn grass (*Aristida*), muhly grass *(Muhlenbergia),* javelina bush (*Condalia ericoides*), squaw bush (*C. spathulata*), and juniper (*Juniperus monosperma*). The soils of this region range from sandy to rocky.

Toads were located and collected at night using a variety of techniques including: (1) pitfall traps, as described by Punzo (1990); (2) road cruising along State Highway 385 as well as several dirt roads throughout the area; (3) on foot, through the use of head lamps; (4) drift fences as described by Huey and Pianka (1983). Time, place of capture, SVL and sex were recorded for each animal and individuals were marked by toe-clipping as reported by Martof (1953) and released for future demographic studies. Pitfall traps were checked at hourly intervals.

Stomach contents were obtained from anaesthetized toads within 8 h of capture using the stomach-flushing technique described in detail by Legler and Sullivan (1979). The stomach contents for each toad were placed in individual glass vials containing 80% ethanol for later identification. Prey items were identified to order and family, depending on the stage of digestion. The information obtained for stomach contents reported in this study represents data from different individuals (no recaptures). For each prey item, length (a) and width (b) were measured to the nearest 0.01 mm (excluding legs and antennae) and volume was determined according to the formula for the volume (V) of a prolate spheroid (Dunham 1983): $V = 4/3\ (a/2)(b/2)^2$. Dietary niche overlap (D) was calculated according to the method of Floyd and Jenssen (1983).

The results for the stomach content analyses are listed in Table 1. An ANOVA (Sokal and Rohlf 1981) showed no overall significant differences as a function of sex ($p > 0.45$) or season ($p > 0.37$). The major prey types during spring and summer months for both species, as indicated by % volume, were beetles (Coleoptera, 33.6 - 34.2%), ants (Formicidae, 16.4 - 21.3%), orthopterans (9.8 - 12.8%), unidentified insects (8.1 - 13.9%) and spiders (8.8 - 13.4%). Termites (Isoptera) comprised a significant proportion of the diet (12.1 - 13.5%) during the spring but decreased markedly (3.4 - 4.2%) during summer months ($p < 0.01$, Two Sample Means Test, assuming unequal variance, Sokal and Rohlf 1981), reflecting differences in the seasonal activities and abundance characteristic of desert termites (Punzo 1974). Nocturnal representatives of arthropods with well known chemical defenses that were commonly found in the study area, such as blister beetles (Meloidae), velvet ants (Mutillidae), stink bugs (Pentatomidae), and millipedes, were not found in any of the stomachs examined. A few centipedes and scorpions were found in the stomachs of *S. multiplicata.* This may be related to the observation that *S. multiplicata* appeared to be more common on rocky substrates which provide more suitable microhabitats for scorpions and centipedes. The data in Table 1 indicate that *S. couchi* and *S. multiplicata* have very similar diets. This is supported by the results found for niche overlap (D = 0.82) which indicate a high degree of dietary overlap between these two species.

The results of this study indicate that although *S. couchi* and *S. multiplicata* are generalized arthropod predators, beetles, orthopterans, ants, spiders, and termites (spring) collectively comprise 82.1 - 93.8% of their total diet. It is well known that the mutual use of similar resources by sympatric species may indicate a potential for competition (Jones 1982). Although overlap is not necessarily proportional to the intensity of competition (Dunham 1983), the high degree of dietary overlap between these two species suggests the potential for interspecific competition. Most amphibians and reptiles exhibit some degree of food partitioning (Schoener 1968) and yet there was little evidence of this in these spadefooted toads. This suggests that competition for food was relatively unimportant in this area over this period of time. The prey of most frogs can be divided into two main categories (Toft 1985): (1) ants and other slow-moving, chitinous arthropods, and (2) all other types. It has also been shown that ants constitute a significant if not dominant component of the diet in many species of bufonids, dendrobatids, and other anurans (Inger and Marx 1961; Toft 1980). This is not true for *S. couchi* and *S. multiplicata,* although

Table 1. Stomach content analyses for *Scaphiopus couchi* (N = 367) and *Spea multiplicata* (N = 293). Data represent different individuals (no recaptures). The results are expressed as number of prey (N), frequency (F, percent of toad stomachs containing a particular prey item), and percent volume (V). There were no significant differences in dietary composition between sexes for both species.

ants are consumed in moderate proportions.

Future studies should investigate possible differences in microhabitat preferences and seasonal activity patterns. In addition, it would be valuable to study dietary preferences and diel activity patterns in allopatric populations and then extend these studies to other pelobatid species.

ACKNOWLEDGMENTS

I wish to thank T. Punzo and J. Bottrell for their assistance in the field, and T. Snell and anonymous reviewers for helpful comments on the manuscript. I am grateful to D. McCarty for access to private property and B. Garman who provided assistance on statistical analyses. A Faculty Development Grant and sabbatical leave from the University of Tampa made much of this work possible.

IDENTITY OF THE GARTER SNAKE *Thamnophis sumichrasti cerebrosus* SMITH

Among the garter snake names that have defied easy allocation is *Thamnophis sumichrasti cerebrosus*, which was described originally by Smith (1942) on the basis of three specimens from Guatemala. The female holotype (USNM 12734) and male paratopotype (USNM 12753) were collected at Esquintla by H. J. Stuart; a male paratype (FMNH 410) bears no locality data more precise than "Guatemala." No additional specimens have come

to light since the description, and *T. s. cerebrosus* has been treated variously as a synonym of *T. fulvus* (Stuart 1963; Rossman 1970 — both by implication), as a subspecies of *T. cyrtopsis* (Rossman 1971), or as a synonym of *T. marcianus* (Webb 1982). Clearly, the identity of this nominal taxon is far from settled.

Unlike his predecessors, Webb (1982) gave a detailed redescription of the type series of *cerebrosus*, and he provided the first photographs of the holotype and paratopotype. Rather than repeat his descriptions here, I will merely point out a few differences I observed, and will provide data on several pertinent features that Webb did not discuss. For the holotype, I recorded 66 (rather than 67) subcaudals and 23 (vs. 22) maxillary teeth; I clearly saw the lateral stripe on dorsal scale rows 2 and 3 (vs. not recognizable), and observed short and narrow black bars preceding the posterior margin of supralabials 2-5 (vs. 4 and 5). The male paratopotype appears to have 146 (vs. 149) ventrals and unmarked supralabials (vs. faint bars on 4 and 5). Although not reported by Webb (1982), this specimen, like the holotype, has 23 maxillary teeth. The other male paratype (FMNH 410) appears to have 78 (rather than 79) subcaudals and, to my eyes, lacks distinct supralabial markings save for a very narrow black bar lying along the posterior margin of supralabial 5 (the epidermal scales are missing and the animal is too discolored by preservative to state with any degree of certainty that 6 and 7 were the same color in life as the temporals). This animal possesses 22 maxillary teeth.

Webb (1982) concluded that the holotype was assignable to *Thamnophis marcianus praeocularis* (on the basis of vertebral stripe width and ventral pattern) with a tendency in ventral pattern toward *T. m. bovalli*. He opined that the two male paratypes differed too much from the female holotype and from each other (and, presumably, from *T. marcianus*), to permit allocation without further study.

The width of the vertebral stripe in the holotype of *cerebrosus* may be similar to that of *T. m. praeocularis*, but the holotype has too few maxillary teeth (23 vs. 27-31), too many ventrals (142 vs. 134-138), and too short a tail (21.6% of total length vs. 24.8-26.8%) to belong to that taxon. In these three specific features, the holotype more closely resembles members of the Tehuantepec population of *T. m. marcianus*. Such an association would also make more sense zoogeographically (*praeocularis* being confined to the Caribbean versant), except that I am not convinced this specimen (any more than the male paratypes) is a *Thamnophis marcianus* of any kind. All three lack any trace of the unique head pattern characteristic of all *T. marcianus* (see Rossman 1971, fig. 2) — including USNM 108598-599 from Aquacate, Chiapas. Moreover, the holotype of *cerebrosus* has a broad muzzle tip (internasorostral contact/nasorostral contact = 137.5%), whereas the muzzle tip is relatively narrow in female *T. marcianus* throughout the range of that species (pers. obs.).

If not a *T. marcianus*, what is *cerebrosus?* Assuming the locality data to be accurate, the only *Thamnophis* species known to occur in the Pacific versant of Guatemala are *T. fulvus* (Webb 1982) and *T. proximus* (UTACV R24817, R26339; unpublished records, courtesy of J. A. Campbell). Another garter snake, *T. cyrtopsis collaris*, which ranges into the interior valleys of Guatemala from Chiapas, México (Webb 1982), must also be considered. All three taxa can be eliminated easily. The lateral stripe is on rows 3 and 4 in *T. proximus*, which also has far more subcaudals (82-98 in females from southern México and Central America; Rossman 1963) and more maxillary teeth (27-34; Rossman 1963). Specimens of *T. cyrtopsis collaris* from southern México and Guatemala also have far more subcaudals (86-92; Webb 1982) and more maxillary teeth (25-28; unpublished data). Finally, *T. fulvus* has an indistinct vertebral stripe and more maxillary teeth (27-30; unpublished data). Moreover, all three of these species usually have eight supralabials, whereas *cerebrosus* has but seven (the six in the male paratopotype appears to represent a fusion of supralabials 4 and 5).

What then can we conclude? Either *cerebrosus* represents a valid taxon, presumably isolated in the foothills on the Pacific versant of Guatemala, or the locality data for all three specimens are inaccurate. At this point, I cannot conclude which alternative is correct, but I feel it is important that the uncertain status of *cerebrosus* be brought to the attention of the herpetological community. Our classification might be more "tidy" if *cerebrosus* were left buried in the synonymy of *T. marcianus*, but to do so would only perpetuate this case of mistaken identity. Perhaps by focusing light on this enigma, someone will be encouraged to conduct fieldwork that might finally resolve the matter.

BEHAVIOR OF HATCHLING DIAMONDBACK TERRAPINS *(Malaclemys terrapin)* RELEASED IN A SOUTH CAROLINA SALT MARSH

Aspects of the ecology and demography of diamondback terrapins *(Malaclemys terrapin)* have been published for populations in Delaware (Hurd et al. 1979), New Jersey (Montevecchi and Burger 1975), Florida (Seigel 1984), South Carolina (Lovich and Gibbons 1990), and Louisiana (Cagle 1952). However, as in most turtle species, very little is known regarding the behavior and ecology of juveniles. Studies of reproductive ecology (Burger 1976, 1977; Burger and Montevecchi 1975; Montevecchi and Burger 1975; Seigel 1980) and hatchling emergence behavior (Burger 1976) have documented the first few weeks of a terrapin's life, but from the time that a hatchling enters the water to approximately the time of sexual maturity, little is known about wild *M. terrapin*.

We have studied a population of *M. terrapin* in Charleston Co., South Carolina since 1983 (Lovich and Gibbons 1990). Like previous investigators (Coker 1906; Hurd et al. 1979) we were intrigued by the

absence of hatchling and juvenile terrapins (0-3 yrs of age) in our sample of over 670 marked individuals, despite repeated efforts to locate them using a variety of collecting techniques.

The objective in this study was to observe the behavior of artificially incubated *M. terrapin* following release into the wild. It was hoped that their behavior would provide clues as to where these animals spend their first few months of life after leaving the nest.

MATERIALS AND METHODS

Nineteen eggs were removed from three *Malaclemys terrapin* nests on Kiawah Island, South Carolina on 21 May 1990. The nests were located on exposed sand dunes with sparse vegetative cover *(Uniola paniculata)* along the Kiawah River. The eggs were returned to the Savannah River Ecology Laboratory (SREL) for incubation at either 27° or 30°C as part of a larger study of terrapin ecology (see Lovich and Gibbons 1990). Eight eggs hatched in late July, 1990. The hatchlings were maintained in an aquarium at SREL, unfed due to the presence of large yolk sacs, for one week prior to being released on Kiawah Island. The mean straightline carapace length (CL) of the hatchlings was 33.4 mm (SD = 1.5 mm, range 32-36 mm). A single individual (36 mm CL) from a clutch hatched in October of the previous year was included in the experiment.

The nine hatchlings were released on 22 August in the salt marsh across the Kiawah River from the nest sites. The release points were located along the shoreline of a small (600 m^2) island in the marsh known to have concentrated nesting activity. The island sustains a few pines *(Pinus taeda)*, live oaks *(Quercus virginiana)* and palmettos *(Sabal palmetto)*, but a dense cover of *Spartina patens* predominates. The marsh around the island is composed of dense to sparse stands of *Spartina alterniflora* that are exposed at low tide. The habitat around the immediate perimeter of the island where the hatchlings were released is the "short *Spartina* high marsh/*Salicornia—Distichlis* marsh" described by Teal (1958). The behavior of each hatchling was monitored by a pair of observers for one hour after being released in the water within 1-2 m of the shoreline or on the island. Releases occurred at 1200 h.

RESULTS

All hatchlings displayed a general avoidance reaction to open water and swam toward shoreline vegetation even when observers were standing on the shoreline in direct view of the animals. The orientation of release, relative to the sun, did not appear to influence this behavior; hatchlings swam toward shore when released on both north and south sides of the island. In addition, upon encountering beached mats of tidal wrack (*Spartina* stems) terrapins immediately burrowed into the mat by pushing the stems apart with their forelimbs. This behavior was remarkably consistent and was repeated by the same animal even when it was pulled out of the mat and allowed to choose again between burrowing and some alternative behavior. Hatchlings released facing away from the island also turned and swam directly toward the shoreline. Hatchlings released on the island within one meter of the line of tidal wrack moved in the direction of the wrack and burrowed. Burrowing behavior always occurred in the tidal wrack at the high tide line. No terrapins were observed to venture beyond this microhabitat into the dry interior of the island.

DISCUSSION

Most hatchling *Malaclemys terrapin* emerge from the nest during the daytime, 1-9 days after hatching (Burger 1977) and move toward the closest terrestrial vegetation. This behavior is consistent regardless of the direction of incline in the terrain (Burger 1976). The apparent negative phototaxis exhibited by this species following emergence may be selected for because of high diurnal predation by shore birds (Burger 1976). In contrast, several other turtle species exhibit positive phototaxis (Anderson 1958), heading straight for the water following emergence from the nest. After entering the water terrapins are rarely seen until they attain sexual maturity some 3-6 yrs later (Lovich and Gibbons 1990).

The only published information on the microhabitat of juvenile *M. terrapin* during the active season is given by Pitler (1985). He observed juveniles with shell lengths ranging from 25-75 mm hiding under "accumulated surface debris and matted *Spartina* grass" in a New Jersey "tidal mud flat." He made 12 observations between 30 May 1979 and October, 1981. Several observations were made of terrapins hiding under rocks, boards, and a low growing *Vaccinium* bush. Lawler and Musick (1972) discovered a 54 mm CL terrapin hibernating in moist sand eight meters from the high tide mark at a depth of about 0.3 m on 7 November 1967 in Virginia. The same individual was periodically uncovered until 23 April the following year to determine depth of hibernation. Vertical and horizontal movements of 2-8 cm were observed.

Our preliminary observations and those of Pitler (1985) both suggest that young *M. terrapin* seek the underside of dense mats of vegetation. We suspect that small terrapins do this for several reasons. First, the tidal wrack and flotsam provide an abundant source of cover to terrapins at sizes when they are highly susceptible to predation by aquatic and terrestrial predators. Second, since the cover accumulates at the high tide line it is the nearest source of periodically flooded microhabitat to the nest site. Third, in addition to providing moist conditions, the summer temperatures under the debris are well below those of the surface outside the mat (pers. obs.). Fourth, numerous small invertebrates are found beneath the mats, providing a potential source of food for young terrapins. Allen and Littleford (1955) noted that newly hatched terrapins were rather indiscriminate in their initial food habits but preferred shellfish and snails *(Littorina irrorata)*. Our observations have revealed high concentrations of small fiddler crabs (*Uca* spp.), square-backed crabs (*Sesarma* spp.), marsh periwinkles *(Littorina irrorata)* and miscellaneous small insects and amphipods under the *Spartina* mats, all potential food items for young terrapins.

Although it seems logical that hatchling and juvenile terrapins might spend their early years under mats of debris in the marsh, we have been unable to locate these smaller individuals despite intensive searches. It is possible that smaller size classes exist at very low numbers due to heavy predation. Although juvenile habitat preferences can only be identified by more thorough behavioral studies, these limited observations do provide evidence that hatchling *M. terrapin* are not averse to temporarily utilizing the microhabitat beneath tidal wrack.

ACKNOWLEDGMENTS

Our research was supported by a grant from Earthwatch Expeditions, Inc. Field assistance was also provided by students and technicians of the Savannah River Ecology Laboratory and the College of Charleston, and J. Schachter. Housing accommodations during our stay on Kiawah Island were provided by M. Permar of Ravenel Associates, R. Kolls and A. Nesmith of Landmark Realty, and J. Middleton of Beachwalker Rentals, Inc.

Access to the island was provided by P. McKinney of the Kiawah Resort Assoc., and T. McAdory and R. Jonathon of the Kiawah Island Community Association. Research was also supported by Contract Number DE-AC09-76SROO819 between the U.S. Department of Energy and the University of Georgia's Savannah River Ecology Laboratory.

OBSERVATIONS OF FORAGING BEHAVIOR IN CAPTIVE JUVENILE *Alligator mississippiensis*

Due to largely nocturnal activity in an aquatic environment, few published observations of foraging behavior among juvenile American alligators (*Alligator mississippiensis*) exist. In a detailed account based on years of field observations, McIlhenny (1935) suggested that juvenile alligators are opportunistic sit-and-wait predators taking any prey which happens to swim past "with a swift side motion of the head". Palis (1989) observed a juvenile alligator apparently attempting to flush prey in emergent vegetation. In conjunction with a food habits investigation of juvenile and sub-adult American alligators (Platt et al. 1990), observations were made of foraging behavior among captive animals.

Four juvenile alligators ($\bar{x}$ TL = 60.1 cm) were collected in July 1988 from the Manchac Wildlife Management Area (MWMA) in St. John the Baptist Parish, Louisiana, USA. They were maintained indoors in a 137 cm diam plastic-bottomed wading pool at 25°C and a water depth of ca. 16.5 cm. Concrete blocks were placed in the pool to provide a basking surface. An acclimation period of two weeks allowed the alligators to become accustomed to, and feed in the presence of, observers. The animals were fed a diet of chopped nutria (*Myocastor coypus*) meat. At the conclusion of the acclimation period, living prey items were introduced and foraging behavior was observed. Prey species offered included crayfish (Cambaridae), mosquitofish (*Gambusia affinis*), sailfin mollies (*Poecilia latipinna*), sunfish (*Lepomis* sp.), and crickets (*Gryllus* sp.). Observations on foraging behavior were made over the next four weeks, under the same conditions as described for the acclimation period.

In taking crayfish, alligators were observed to crawl along the bottom of the pool, moving the head from side to side in a slow horizontal sweeping motion with jaws slightly agape. When contact was made with a crayfish an instant attempt was made to seize it. If successful the alligator immediately surfaced, holding the crayfish in its jaws. Small (ca. < 4.5 cm TL) crayfish were swallowed with no further manipulation. Larger crayfish (maximum = 13 cm TL) were aligned between the jaws on an axis perpendicular to the head and then crushed repeatedly until the exoskeleton was reduced to a pulverized mass. The crayfish were then repositioned and swallowed tail first. We suggest that visual cues were unimportant in this foraging behavior as the nictitating membrane was observed to cover the eyes while the alligator was submerged. This corresponds to the observations of Fleishman and Rand (1989).

Our observations of underwater prey capture by American alligators indicate the necessary tactile stimulation was provided through direct contact with the prey. Crayfish often were captured while motionless and pieces of nutria meat placed on the bottom of the pool also were readily located. Additionally, juvenile alligators in Florida were reported by Fogarty and Albury (1968) to consume large numbers of aquatic snails (*Pomacea paludosa*), a relatively immobile prey species unlikely to be located by water movements. It also is possible that olfactory cues are important in underwater prey capture (Fleishman and Rand 1989).

A sit-and-wait behavior similar to that described by McIlhenny (1935) was used to capture mosquitofish, sailfin mollies, and swimming crickets. In addition, a large moth (Lepidoptera) and several cockroaches (Blattidae) that inadvertently fell into the pool also were taken using this

behavior. The alligators remained motionless and partially submerged with only the dorsal surface of the head exposed. To capture prey, alligators lunged forward, simultaneously twisting the head to one side while biting at the intended prey. The rear feet often were used to push off the bottom and the tail was thrust downward, providing additional leverage and making lunges up to 25 cm possible. It appeared that surface water movement generated by the prey was important in eliciting feeding behavior. These observations support the experimental evidence of Fleishman and Rand (1989).

Sunfish were not taken by the alligators in this study despite being present in the pool for a period of several weeks. We suggest that sunfish, which do not swim continuously near the surface in the manner of cyprinodontid and poeciliid killifishes, fail to provide the water movements that appear necessary to trigger the feeding response by alligators. Werner (1977) noted that sunfish generally occupy a niche in the deeper areas of the littoral zone, an area where alligators do not seem to forage. This observation is supported by Platt et al. (1990) who failed to find any evidence of sunfish in the stomach contents of 101 juvenile alligators from MWMA, despite their relative abundance (Hastings 1987). Tail wagging (Jones and Hayes-Odum 1990) was not observed in this study.

Alligators were observed to leave the water readily and capture crickets placed on the basking platform. This capture often involved a short chase. Similar observations have been made of captive *Caiman crocodilus* by Jackson et al. (1974). These observations and the large number of terrestrial insects found in the stomach contents of wild juvenile alligators by Platt et al. (1990) strongly suggest that alligators readily forage along the land/water interface and insect remains found in the stomach contents are not simply due to secondary ingestion from anurans as suggested by Neill (1971).

In summary, these observations further support the contention of Magnusson et al. (1987) that unlike most reptiles which have fairly stereotyped foraging behavior, crocodilians have highly specialized foraging modes which they can readily change as the situation warrants.

ACKNOWLEDGMENTS

This research was supported by the Louisiana State Board of Regents through the Rockefeller Trust Fund. We appreciate the cooperative assistance of the Louisiana Department of Wildlife and Fisheries and Southeastern Louisiana University personnel, especially Jerry Wagnon, Robert Love, and Robert Hastings. Mike Leggio, John Wilhelm, Lance Fontenot, and Mike Knife kindly assisted in collecting prey items and alligator maintenance.

FOOD HABITS OF WESTERN TOADS (*Bufo boreas halophilus*) FORAGING FROM A RESIDENTIAL LAWN

Toads (*Bufo boreas halophilus*) occur in suburban areas of central and southern California where residential landscaping and irrigation practices provide adequate food and shelter for survival. This study describes the food habits of toads foraging from a residential lawn in Bakersfield, California, a disturbed habitat. Previous studies have reported the food habits of western toads from various native localities (Campbell 1970; Cunningham 1954; Livezey 1961; Schonberger 1945; and Schuierer 1961).

MATERIALS AND METHODS

Fecal pellets egested by six adult toads (*B. b. halophilus*) were collected from a 0.06 ha residential lawn (hybrid bermuda grass, a cultivar of *Cynodon dactylon* x *C. transvaalensis*) in Bakersfield, California (Kern County, 35°21'15"N, 119°09'00"W). Pellets were collected daily between 0500-0800 h from mid-May through mid-July of 1989 and 1990. These were rinsed with water and chitinous arthropod fragments were collected on a 1 mm mesh screen. Fragments from individual pellets were transferred to filter paper, dried for 24 h at 68°C and sorted by taxa. Identification was aided by using intact reference specimens obtained locally.

The frequency of arthropod taxa was determined by direct inspection of egested chitinous fragments. The biomass and caloric content of arthropods was determined using fresh (nonegested) specimens. Live specimens were obtained from the turfgrass, weighed to the nearest 0.1 mg, and dried at 68° C to constant weight. Caloric values (kcal/g) were determined with a Parr oxygen bomb calorimeter (Dimmitt and Ruibal 1980).

RESULTS AND DISCUSSION

A total of 6,946 arthropods were collected from 320 fecal pellets (Table 1). Principal taxa included Crustacea, Coleoptera, Hymenoptera, Dermaptera, Arachnida, and adult Lepidoptera. Coleoptera and Crustacea were found in over 50% of the pellets examined. The mean number of arthropods per pellet was 21.71 ± 11.93 ($\bar{X} \pm$ S.D.).

Studies of *B. boreas* in native habitats indicate that Coleoptera, Hymenoptera, and Diptera comprise the principal arthropod taxa ingested. In Oregon and Washington, Coleoptera and Hymenoptera (Formicidae) comprised 51.3% and 43.5% of the diet for *B. b. boreas* (Schonberger 1945). In Boulder County, Colorado the *B. b. boreas* diet included 71.0% Hymenoptera (Formicidae) and 14.6% Coleoptera (Campbell 1970). In Inyo County, California Hymenoptera and Diptera comprised 82.4% and 10.6% of the diet for *B. b. exsul* (Schuierer 1961). Adult *B. b. exsul* averaged 21.0 food items per stomach (Livezey 1961).

Calorimetric analyses revealed differences in the food value of selected arthropod taxa. Although isopods (*Armadillidium* sp.) and scarabaeid beetles (*Phyllophaga* sp.) were dominant in fecal pellets (31.2% and 26.1%, respectively), they were not of comparable caloric value (Table 2). Isopods and scarabaeids were calculated to represent 10.4% and 69.6% of the caloric intake, respectively. Differences in caloric value are attributed, in part, to the mineral (ash) content of exoskeletons (Table 3). Isopods have a much higher ash content than other food items (e.g., insects), hence they have a much lower caloric value.

The assimilation efficiency (calories ingested not recovered in feces) is known to vary between arthropod taxa, decreasing as the proportion of chitin in arthropod exoskeletons increases (Dimmitt and Ruibal 1980). Assimilation efficiencies were not quantified in the present study, but it is suspected that the assimilation efficiency for isopods may be much lower than that reported for other arthropods.

ACKNOWLEDGMENTS

I thank two anonymous reviewers for comments made on an early draft of this manuscript.

NOTES ON AGGRESSIVE BEHAVIOR OF THE GOPHER TORTOISE

Male tortoises of the genus *Gopherus* are frequently cited as attempting to overturn other males by prying them up with the gular extension of the plastron. Review of the literature, however, reveals that interpretations are based on hearsay, personal communications, or observations of captives. No firsthand accounts of overturnings in the wild have been published for any of the four *Gopherus* species, with the possible exception of Grant (1936), who may have been watching captives. Here we report observations of fighting in wild and freshly caught male gopher tortoises (*G. polyphemus*), briefly review the literature, and discuss the consequences of overturning.

On 8 January 1989 JPH and RK watched two male gopher tortoises fighting in a sand firelane of Archbold Biological Station, Highlands County, Florida. The encounter was already underway at 1147 h EST when we found the animals and it concluded at 1218 h when the pursuing animal abandoned the chase. The tortoises did not, however, fight continuously during these 31 min, but rather stopped frequently.

Three principal action patterns were used. (1) In the "push" the tortoises faced one another with heads retracted but not entirely within the shells. Each animal thrusted with its hindlimbs, resulting in both tortoises rising off the substrate anteriorly with the gular extension of the plastron pressing firmly against some anterior part of the opponent. Because the forelegs were often dangling in the air, we concluded that the major thrust probably came from the hindlimbs. While the foreparts of their bodies were thus off the ground, the opponents actively moved the forefeet toward each other, but these motions rarely made contact. (2) "Jerk up" consisted of hooking the gular extension under the other animal (several times under the anterior edge of its carapace) and jerking up suddenly. We could not determine exactly how the thrust of this upward jerk was effected, but it had to come almost entirely from the hindlimbs. If the opponent is anchored by its hindfeet and the thrust is obliquely upward (as opposed to being truly horizontal), then there will be a vertical vector component to the thrust. One tortoise succeeded in upturning its opponent in this way, but the opponent managed to stop the motion as it was on its side and about to roll on its back, and then eventually righted itself. (3) "Kick sand" occurred when the animals were head-to-tail, with the lead tortoise throwing sand toward the face of the following animal. Kicking sand occurred when the tortoises were stationary, and also when one animal was retreating from its opponent during the final chase that ended the encounter. We were unable to see with certainty which limbs were used for kicking sand because the kicking was done on the side away from us. However, the kicking animal did end up with sand on its carapace (confirmed in our photographs), which suggests that the forelegs were used.

Observations on gopher tortoises temporarily held for marking and measuring at the Station by JNL further support the foregoing descriptions. On two occasions (23 July 1981 and 3 April 1982) one male was seen to overturn another during fighting. On 26 March 1973 two captive males loose in a large laboratory room fought off and on all day. The tortoises engaged in pushing head-on with each animal rising anteriorly and appearing to try to get its gular process under the other's shell. Similar pushing and hooking with the gular extension was also directed toward the side of the opponent. Futhermore, the attacking tortoise often rose up on the hind quarters, with front quarters low, to better pry up on the other with the gular process. Fighting bouts lasted minutes, then stopped for a while, only to continue again.

The earliest report of male fighting in *Gopherus* may be by Fletcher (1899), who described pushing and overturning in male gopher tortoises, but then added that the only fight he actually witnessed was between two (captive?) females, one of which killed the other. Carr (1952) found this and other claims of Fletcher to be preposterous. Camp (1916) stated that captive desert tortoises (*G. agassizii*) ram one another with the gular projection, which does the opponent "no damage except sometimes to turn him upon his back." Miller (1932) reported similar findings in this species, also apparently in captives, and added that "the inverted foe is seldom left helpless...possibly his [the victor's] sportsmanship induces him to help his rival up so that they can enjoy another bout." Grant (1936) also reported pushing with the gular extension in desert tortoises, in which the male "lifts and twists, often upsetting his antagonist," which may die in the sunlight if unable to right itself; this description suggests that the observations may have been made by the author himself, possibly on captive animals. In a popular article Cassell (1945) provided a similar description, later repeated by Pepper (1963) in the same magazine, the latter clearly based on captive animals. Legler and Webb (1961) reported ramming in captive Bolson tortoises (*G. flavomarginatus*). Rose (1970) conducted experiments with Texas tortoises (*G. berlandieri*), presenting them with a plaster model having chin-gland secretion (a mixture of fatty acids) smeared on it; 23 of 37 captive males rammed the model and six turned it over. Not one of the foregoing reports is clearly based on first-hand observations in the wild, and several seem to be based on hearsay.

Weaver (1970) reported seeing one *G. berlandieri* "attempting" to overturn another (no details), but apparently did not witness an actual overturning. The only overturning documented was in a personal communication from K. G. Metocha, where the observer himself interrupted the fight and turned one tortoise over, which was then overturned again by the opponent as the tortoise was righting itself.

The only unambiguous reports we have found of overturning in the wild are personal communications cited by Douglass (1976, 1986) for the gopher tortoise. He recounted some of JNL's observations (above) and added briefer reports by J. W. Lang, A. R. DeGange, and T. Allen and D. Austin. Each of these observers apparently witnessed a wild tortoise overturn its opponent at least once. If the early reports can be believed, males of all four species of *Gopherus* ram the opponent with the gular extension and use it as a lever to overturn the opponent.

Overturning of a tortoise can place it in serious thermoregulatory stress (Douglass and Layne 1978). If the animal cannot right itself it risks death, especially in direct sunlight where the radiation load is high. Although the gopher tortoise is active at the hottest times of day, two individuals died from thermal stress on summer afternoons, one within 5 h (Douglass and Layne, 1978). JNL has found that this species can sometimes right itself on a grassy substrate but not in the loose sand of its natural habitat. Death resulting from exposure to sunlight was also reported for *G. berlandieri* (Grant 1960), where an individual died in 10 min at an air temperature of 39.4°C. Similarly, Ortenburger and

Ortenburger (1927) reported that all (number unspecified) *G. agassizii* in a cage completely exposed to the sunlight died within a day, and a tethered animal that got tangled and was unable to reach shade died before noon.

Kicking sand appears never to have been reported before in fighting male *Gopherus*. Our observations of this act show it is not merely a consequence of rapid locomotion away from the opponent but is also done by stationary gopher tortoises. One of us (JNL) has observed sand kicking as a regular feature of burrow maintenance by the entering gopher tortoise. This behavior was associated with tortoises being chased into their burrows when he (JNL) attempted to capture them for marking. He has the impression that the forefeet are always used for this purpose. Thus, one action pattern (sand kicking) is used in three contexts: burrow maintenance, predator repulsion, and intraspecific aggression.

NOTES ON EARLY SPRING PARASITES AND PATHOLOGIES OF OKLAHOMA *Crotalus atrox*

A study of western diamondback rattlesnakes, *Crotalus atrox*, collected in the spring of 1987 and 1988 during Oklahoma's rattlesnake round-ups presented an opportunity to examine parasites and pathologies of this species from three localities: Waurika (Jefferson Co.), Waynoka (Major Co.), and Okeene (Blaine Co.).

METHODS

Snakes sampled were collected within a 30-mile radius of each locality by area residents two weeks prior to the public event (at which time snakes may be brought from various localities). In 1988, viscera from 296 snakes (128 male:168 female) were collected immediately as snakes were killed by decapitation, and were preserved at once by submerging in 10% formalin. After formalin-fixation for several days, viscera were soaked for 24 h in water, then transferred to 70% ethanol for storage. Viscera were referenced to previously weighed and measured (several parameters) snakes by recovery of a numbered plastic tag inserted deeply into the esophagus of each live snake examined. In 1987, viscera from 60 (22:38) representative Waynoka snakes were similarly collected, but were not tag-referenced to individual living snakes.

Viscera were examined during the summers of 1987 and 1988. G-I tracts were slit lengthwise from the esophagus to the rectum, and macroscopically examined for parasites, pathologies, food, and fangs. Samples of tissue and gut contents for microscopic examination were removed and transferred to vials of ethanol. Gut contents samples were examined and photographed at 160x or 1000x magnification using Kodacolor-200 film and a Zeiss "Standard-17" microscope with Contax RTS camera. Photos were printed to 86 X 125 mm size. Representative tissue samples were sectioned, stained, and examined at the Research Animal Diagnostic and Investigative Laboratory, College of Veterinary Medicine, Univ. of Missouri (Columbia) (Accession number 003155-88). Parasite indications were observed in 41 snakes (11.5%), though as will be elaborated below not all of these can be unequivocally designated as parasites of *C. atrox*. All material is presently maintained in the University of Kansas Biology Teaching Collection.

RESULTS

Waurika. Results are summarized in Table 1. Pulmonary aspergillosis was evident as severe, diffuse interstitial and alveolar granuloma with numerous hyphae and terminal conidia. The multiple intraserosal trematode cysts recorded from a single male were clustered around the small intestine. A male (1220 mm SVL, 1520 g) contained numerous pentastomid eggs, and 14 adults *(Porocephalus crotali)* were observed in the lung (see Self and Kuntz 1967).

Okeene. Results are summarized in Table 2. The intraserosal trematode cysts recorded were clustered primarily around the animals' small intestines and kidneys, but occasionally were found in the adjacent mesentery and the serosal surface of a fat body (one animal). The two males containing pentastomids [*Porocephalus*

crotali (see Self and Kuntz 1967)] were not equivalently infected. One (1168 mm SVL) contained 36 adult and subadult pentastomids in the lung; additional subadults (ca. 20 mm) were also seen in the coelom and under the mesentery adjacent to the large intestine. Total weight of all pentastomids in this animal was 8.3 g. The other male (SVL not recorded) contained one adult pentastomid (wt. 0.2 g) in its lung.

Waynoka. Results are summarized in Table 3. Pentastomids [*Porocephalus crotali* (see Self and Kuntz 1967)] were recorded from two females. One of these (921 mm SVL) contained 26 pentastomids (adults and subadults—21 within the lung, 4 attached to its serosal surface, and 1 attached to a kidney). Weight of the 21 from within the lung was 4.6 g. The other female (930 mm SVL) contained 25 pentastomids (wt. 5.0 g) in the lung.

Again, the multiple intraserosal trematode cysts were found clustered mainly around the small intestine and adjacent coelom wall. Additionally (in one male) cysts were adherent to the gall bladder. The female containing trematode cysts was non-reproductive. An unidentified tapeworm was found in one snake. No pentastomid eggs were noted.

Table 1. Waurika Summary.

DISCUSSION

The Order Coccidia contains 25 genera (Hammond and Long 1973; Olsen 1986), two of which are *Isospora* (oöcysts with two sporocysts, each containing four sporozoites) and *Eimeria* (oöcysts with four sporocysts, each containing two sporozoites). *Isospora* is common in reptiles and *Eimeria* is quite common in mammals, and is not uncommon in snakes. Unfortunately, formalin fixation of the viscera made it impossible to distinguish between oöcysts of these coccidial genera. Therefore it is not possible to accurately determine the percent of snakes that were infected with *Isospora*. Several viperid–murid life cycles have been demonstrated for coccidians (see Wacha and Christiansen 1982; Haefner and Frank 1984; Upton and Barnard 1988), so this is not unexpected.

Pentastomid ova were found in Okeene and Waurika snakes, but none was found in Waynoka snakes. Waurika is located in south-central Oklahoma, whereas the other two localities are north-central. It is therefore unlikely that this difference is meaningful. Adult pentastomids were observed in one Waurika snake (male), two Okeene snakes (male), and two Waynoka snakes (female). Pentastomids are not uncommon parasites of snakes, and fairly large infestations seem not to cause host debilitation (Self and Kuntz 1967; Self 1969; Cooper 1984).

Intraserosal trematode cysts (Hoff et al. 1984) were identified almost exclusively from males (14 of 16 instances); of the two females, one was non-reproductive. The most common site for these cysts was the serosal surface of the small intestine. Trematode ova were found in seven animals (five of them male; one female was non-reproductive). Lyon (1986) documented helminths from six Idaho lizard species, two genera of which (*Crotaphytus* and *Cnemidophorus*) are potential prey of Oklahoma *C. atrox*. If lizards are part of the life cycle of these parasites in Oklahoma (a likely assumption), our data would indicate differential predation by the sexes of *C. atrox* in late summer and fall.

Keenlyne (1972) reported differences in the summer feeding behavior of gravid female (versus male and non-reproductive female) *Crotalus horridus* in Wisconsin. Gravid females did not feed during the later stages of embryogenesis. As reported separately (Fitch and Pisani, in press), most of the female *C. atrox* in the populations reported here seem to follow an annual reproductive cycle. If reproductive females of this species follow the observed pattern of its congener (a pattern also reported for gravid *Agkistrodon contortrix*; Fitch and Shirer 1971), this could explain the observed differential trematode parasitism.

We additionally offer another possible, though conjectural, hypothesis for this observation. It is probable that the two lizard genera mentioned above commence fall dormancy earlier than does *C. atrox*, and that some individuals may select hibernation sites around *C. atrox* den sites. If male rattlesnakes return to den sites earlier than females, they may consume these lizards as their final fall meals, rendering them more susceptible to trematode infection. These two hypotheses are not mutually exclusive.

Finally, it is also conceivable that our observed ratio is a statistical artifact of the small percent of snakes overall that were recorded with pathologies. While the total number of snakes with pathologies is small, the strong bias observed is nonetheless interesting in light of the foregoing.

Pulmonary aspergillosis was seen in nine snakes from Waurika and Waynoka, but in none from Okeene. As remarked above for pentastomids, we feel this locality difference is not meaningful.

These findings are presented with the intent of providing a spring reference point for further and more detailed work. The life history of *Crotalus atrox* is not well known, and it would be instructive to follow the parasite cycle of this species through several years (a project we are presently not in a position to pursue).

ACKNOWLEDGMENTS

This study was funded by a grant from the State of Oklahoma Department of Wildlife Conservation Non-game Program (grant 205-320-6188) to Pisani and Henry S. Fitch, who together collected the samples reported upon here. Hank

Prepublication Announcement

Herpetological Circular No. 20

AGE DETERMINATION IN TURTLES

George R. Zug

A complete and detailed look at techniques used to determine the age of turtles, as well as a comparison of their effectiveness. The first section deals with known-aged samples via mark-release-recapture, and captive rearing; the second section looks at measures of size as a substitute for age, using body length or mass, and lens mass; a third area of this booklet addresses incremental growth markers for age determination with respect to scute growth zones, claws and rhamphothecae, and skeletochronology; and a fourth part covers age estimation through structural modifications as revealed by scute polishing, skeletal changes, and coloration changes. Bibliography. August 1991. 28 pages. ISBN 0–916984–24–9.

Prepublication price $4.00
After October 15, 1991 $5.00

Orders may be sent to the Society Treasurer, Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45046 USA.

Guarisco assisted at Waurika. We thank John Skeene for advice and logistic support through 1988. Members of the Oklahoma Herpetological Society helped in various capacities at the hunts. Andrew Grady, DVM (Univ. of Missouri, College of Veterinary Medicine, Columbia) provided identifications of aspergillosis, and trematode cysts. James Bresnahan, DVM (Animal Care Unit, University of Kansas, Lawrence) generously provided work space and access to photo equipment. James L. Christiansen, Richard Montanucci, and anonymous reviewers provided helpful discussion of parts of the data.

Many persons at the hunts generously contributed time, animals, and information to us. While it is not possible to list all these persons, we would like to acknowledge the following. Waurika: Tommy Martindale, and members of the Waurika JCs; Okeene: Lee Laubach, Gary Cypert, Ken Westfahl, Paul Johannesmeyer, Peppy Wenglarz, Bob Jenni, and the Okeene JCs; Waynoka: Bill Strond, Mildred Sampson, Irene ("Sam") Danner, Bobby Sutherland, and members of the Waynoka Saddle Club. A special note of thanks is reserved for Leo Sutherland, recently deceased, without whose acceptance and help during our 1987 pilot study and thereafter this work would have been most impractical.

THE FIRST REINTRODUCTION OF BLACK CAIMAN, *Melanosuchus niger*, INTO THE WILD

The black caiman (*Melanosuchus niger*) is a large crocodilian found throughout the Amazon River basin, the upper Essequibo and Berbice drainages in Guyana, and in coastal French Guiana. Owing to extensive commercial hide hunting which began in the 1940s, the black caiman has

suffered a dramatic decline in numbers and today is one of the most endangered of the New World crocodilians. Today, black caiman principally remain in small isolated populations and have been extirpated or are very rare over much of their former distribution (Plotkin et al. 1983). Other than the legal prohibition of hunting, which rarely has proven effective, virtually no conservation measures have been initiated in any of the countries where this species is found (Groombridge 1982). In Bolivia, the populations of black caiman have been described as being in danger of extinction (King and Videz-Roca 1989).

In 1989, a group of captive black caiman that were being maintained on the Hacienda El Caimán in northern Bolivia was offered for use in conservation programs. The black caiman on the hacienda had been collected during the late 1970s from the vicinity of Santa Rosa, Reyes and San Borja in the Bolivian Beni region. They were intended to form a breeding nucleus for a commercial farming operation. However, due to poor breeding success and financial difficulties, the owners were unable to keep the entire group and offered to donate a portion of the animals for a restocking project.

In August 1989, the German organization Aktionsgemeinschaft Artenschutz (AGA) offered financial support to transport the caiman for release back into the wild. The organization of the program in Bolivia was undertaken by the Asociación Boliviana Pro-Defensa de la Naturaleza (PRODENA). The Beni Biological Station, located in the Beni Department ca. 50 km east of San Borja, was chosen as a release site because it offered the best chances for protecting and monitoring the caiman after release. The area also provided an abundance of good habitat and was where some of the *Melanosuchus* stock kept on the Hacienda El Caimán originally came from.

The caiman were released in Normandía lagoon, a large (ca. 578 ha), shallow lagoon located close to the main biological station headquarters. Other release sites were considered to be unsuitable because of the possibility that natural black caiman populations may have been present and, without pre-release data from these lagoons, the subsequent conservation benefits of the release program could not be determined. Furthermore, the possibility of introducing unknown pathogens from the captive animals into the wild population had to be considered. Normandía lagoon was chosen because of its proximity to the park headquarters, facilitating control and population monitoring operations, and because the lagoon's population of *Caiman crocodilus yacare* had been well studied over a three year period immediately prior to the planned release of *Melanosuchus*.

The operation began on 26 June 1990 on the Hacienda El Caimán. Twenty-five adult and subadult caiman (1.5 - 2.9 m long; 6 males and 19 females) and eleven hatchling and yearling caiman were captured, measured, and marked (monel foot tags and tail scute notching).

All the caiman except the hatchlings and yearlings were released in Normandía lagoon on 3-4 July 1990. Apart from a few minor scrapes, all caiman appeared to be in excellent shape when turned loose. Within days of the release the first nocturnal survey was conducted to begin the monitoring effort. Continued monitoring of Normandía lagoon will be conducted by personnel of the Beni Biological Station. Population trends of both *Caiman crocodilus yacare* and *Melanosuchus niger* will be determined, and there will be intensive nest monitoring during the reproductive season (late October to early March).

The hatchling and yearling *Melanosuchus* were placed in a small artificial lagoon at the Biological Station headquarters. They will be reared there until they reach a length of ca. 1 m and then released into the wild.

This reintroduction effort demonstrates the increasing interest of a number of Bolivian institutions in addressing the country's wildlife conservation problems.

TECHNIQUES

IDENTIFYING INDIVIDUAL SPOTTED SALAMANDERS BY SPOT PATTERN

Conventional marking techniques for amphibians are not considered adequate for salamanders (Ferner 1979). Since Ferner's summary the only new marking technique that has been proposed for salamanders is that of fluorescent marking (Taylor and Deegan 1982; Nishikawa and Service 1988). This technique individually marks salamanders, but the markings usually do not last longer than a year (Nishikawa and Service 1988).

This paper describes a technique in which individual spotted salamanders (*Ambystoma maculatum*) can be recognized by their spot pattern. The spot pattern is described by the number of spots on defined areas of the animal, eliminating the need for drawings or photographs. For this technique to be valid, each salamander must have a unique spotting pattern and its pattern must not change ontogenetically. The advantages of using natural variation to identify individuals are that salamanders are not damaged in any way and that individuals can always be recognized once the spot patterns are recorded. These data can also provide detailed information on the natural variation of spot numbers.

In this identification technique, all individuals with the same "head patterns" are

classified in a single group. This divides similar-looking salamanders into manageable groups. Individuals with the same head pattern can be further classified by the snout-vent spot counts, "neck" spot counts, and sex. The head pattern is described by summing spot numbers on four regions of the head. The four regions of the head are formed by the gular fold, the fold between the angle of the jaws, and an imaginary line drawn down the center of the head. The "neck" area is between the gular fold and the first costal groove posterior to the forelimbs. The sum of spots on the left and right side of this neck area are recorded. The snout-vent spot counts are from the tip of the snout to the posterior end of the cloaca; the sum of the left and right sides is recorded.

The method used to describe spots in between two regions (e.g., between the "head" and "neck," or in the center of the "head," "neck," or S-V regions) is by counting that spot as 1/2 in each of the regions. This datum is important to record, because it rarely occurs and is usually distinctive to the individual. The only exception to this rule is when a spot overlaps from the snout-vent area onto the tail; then the whole spot is counted as one in the snout-vent count. This is done because spots commonly overlap those two regions.

This technique was tested with two populations of spotted salamanders in Massachusetts. Of 174 individual salamanders caught at a site in Lenox , 97% could be identified using the system of spot counting; drawings and photographs of each specimen served as a reference. Of 70 adult individuals caught leaving a pond in Westport, 97% were individually unique as determined by this technique.

To help determine whether or not a salamander is a recapture, spot data should be organized in a notebook with a separate page for head pattern. Organized this way, many oddly patterned individuals are isolated and individuals with common patterns are divided into manageable groups. For example, the 174 individuals of the Lenox population showed 47 different head patterns; 27 individuals (15%) had unique head patterns. The most common head pattern was shared by 21 individuals. The data can also be entered into DBase (or other programs) and sorted to determine recaptures.

The technique described here is a time-efficient way to describe spot patterns and successfully identified 97% of the individuals in a population. Subjectivity is eliminated in describing spot patterns because only numbers of spots are used. If the spotting pattern does not change ontogenetically once an "adult" spot pattern is established, then an individual can be recognized throughout its life. Using patterns to identify salamanders also provides detailed information useful in describing intra- and inter-population variation.

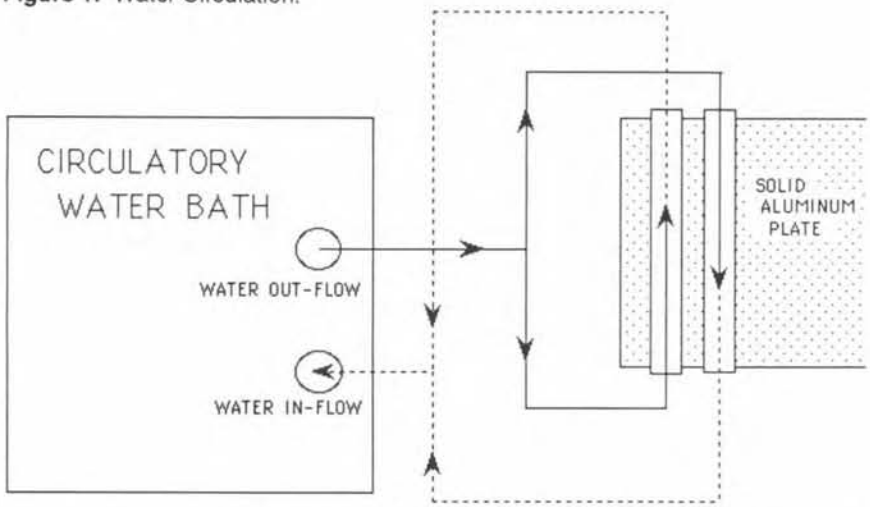
AN IMPROVED LABORATORY APPARATUS FOR EXAMINING THERMAL PREFERENCES OF REPTILES



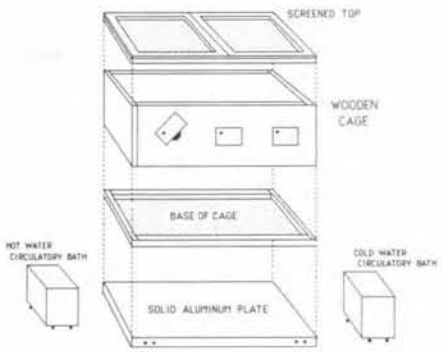
Studies of the thermal preferences of animals often require a consistent and predictable laboratory thermal gradient. Although several equipment designs have been described for use with reptiles (e.g., Dial 1975; Gregory et al. 1982), most produce temperature gradients that may be difficult to control or maintain. This paper describes an apparatus that uses circulating hot and cold water to generate an easily controlled and consistent temperature range for examining laboratory thermal preferences of reptiles. The design is similar to that described in the botanical literature (Cannefax 1962; Wagner 1967; Barbour and Racine 1967; Colosi 1975). An apparatus that provides the same and non-variable temperature range may be important for repeated experiments. Constant temperatures may also be important to certain experimental designs where it may not be possible to measure body temperature. For example, Lutterschmidt and Reinert (1990) measured substrate temperature to avoid physioloigcal responses resulting from the effects of surgically implanted transmitters or disturbance of reptiles by cloacal probing.

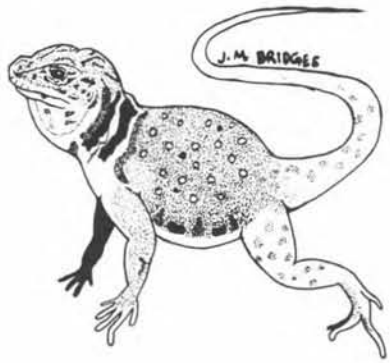
The gradient of this apparatus is generated by heated and refrigerated circulatory water baths (Cole Parmer) attached to opposite ends of a 152 x 30 x 2.54 cm solid aluminum plate. The plate has two grooves cut into the underside (3 cm apart) along the width of the plate at each end. Copper tubing is inserted into these grooves for the circulation of water. This arrangement of tubing allows the circulation of water to flow in opposite directions (across the width of the plate) to generate a constant temperature from front to back and a continuous gradient along the plate (Fig. 1).

A wooden frame with a thin sheet of aluminum attached to the bottom side (resting on the aluminum plate) may serve as a base and container to hold the gravel substrate (Fig. 2). A wooden box (cage) of dimensions 148 x 30 x 31 cm fits snugly into this wooden frame. The wooden cage has small circular access ports (diameter of 8 cm is suggested) cut into one of the length sides. The ports have covers which may be swung open for easy access with a thermistor probe to obtain substrate temperatures without disturbing the reptile. A wooden and screened top is hinged to the wooden cage (Fig. 2). A light source may be suspended above the gradient to provide a uniform light intensity throughout the gradient (Justy and Mallory 1985). This entire apparatus (except circulatory baths) is housed within a larger insulated wooden box to eliminate temperature changes as a result of ambient temperature variation. This structure can be lined with styrofoam or fiberglass insulation.

Some studies of reptilian thermal biology (e.g., Stewart 1965; Kitchell 1969; Gatten and McClung 1981) have used thermal gradients produced by heat lamps and dry ice. Thermal gradients generated by such methods may be easily influenced by ambient temperature fluctuation if the gradient is not well insulated. In addition, insulation of a gradient that uses heat lamps and dry ice may be difficult, if not impossible, because of its design. A thermal gradient that uses dry ice to gen-

Figure 1. Water Circulation.





erate the lower temperatures may also require much maintenance. Conversely, gradients that use heated and refrigerated circulatory baths may easily maintain desired temperatures for long periods of time with little maintenance.

Daily readings of the apparatus described here showed stable substrate temperatures along the gradient for ca. two months of data collection. The mean temperatures (n = 52) at the warm end, middle, and cool end were 45.8°C (SE = 0.143), 29.6°C (SE = 0.145), and 14.7°C (SE = 0.151), respectively. Temperature settings of the heated and refrigerated circulatory baths were ca. 80.0°C and 5.0°C, respectively. The difference in temperature between the gravel substrate and the water or methanol-water mixture (in circulatory baths) is due to inefficiency in conduction. However, once water temperature is adjusted to generate desired substrate temperatures, the gradient temperature range will remain relatively constant even with moderate variation in ambient temperature

The thermal apparatus described in this paper may be a preferred design for long-term studies of reptilian thermal biology. It may provide a non-variable and continuous thermal gradient for almost any biological temperature range, depending on limitations of circulatory baths. However, this apparatus has an important disadvantage of expense. Gregory et al. (1982) describe a well designed thermal gradient (which uses heat lamps and dry ice) with an expected cost of $1600. The gradient described in this paper is considerably more expensive, ranging from $2500 and $4400, due to the cost of two circulatory baths.

*excluded from calculation of mean activity area.

A RADIOTELEMETRY IMPLANT TECHNIQUE FOR USE WITH *Bufo americanus*

Tracking amphibians via radiotelemetry has been hindered because of the small size of many species and difficulties in attaching a transmitter. A rubber harness has been used with *Bufo bufo* (van Nuland and Claus 1981) and a Velcro® sew-on with *Rana palustris* (Johnson 1984) but my efforts to duplicate both methods with *Bufo americanus* were unsuccessful. Despite several design changes in the method of van Nuland and Claus (1981), skin abrasion around the limbs and animals slipping out of the harness were problems. A harness made of girdle material (Kingsmill 1990) may resolve these problems. The sew-on Velcro® method (Johnson 1984) involves sewing a piece of Velcro® to the dorsum of the animal. In addition to being traumatic for toads, this method resulted in bacterial/fungal infections under the Velcro® patch.

Reported herein is a surgical implant technique for toads which overcomes the problems of external attachment but is subject to limitations on size of the transmitter and the ability of the incision to heal. The procedure probably has limited application to frogs because of their thinner skin.

Internal loop SM1 transmitters weighing 0.06 g were purchased from AVM Instrument Company, Ltd. (2356 Research Drive, Livermore, California 94550) and used with either a mercury (Hg312) or lithium (Li803) battery depending on the mass of the animal. The battery-transmitter units were assembled so as to minimize the height of the package. The assemblage was first coated with a 1:1 mixture of paraffin-bee's wax to facilitate battery replacement, then two thin layers of dental acrylic and a coat of bee's wax. The final package had a mass of 1.8 - 2.3 g. Individual toads were anesthetized in 0.01% MS-122 (tricaine methanesulfonate) for 15-20 minutes. After washing the lateral-abdominal area with disinfectant (Betadine® and alcohol), a 15-20 mm longitudinal incision was made through the skin 1-2 cm left (or right) of the vertebral column. The anterior end of the incision was at a level approximately half way down the vertebral column. The transmitter was soaked in ethanol for 30 minutes, rinsed in sterile distilled water and inserted I.P. The incision was sutured. After applying more disinfectant, several layers of New Skin® (New Skin Company, Cody, Wyoming 82414) were sprayed on the incision to facilitate healing. Within 24 h, individuals were returned to the point of capture.

Six individuals (Table 1) were monitored with a LA12-DS receiver (AVM Instrument Co. Ltd.) for 12-25 days between June-September 1988. Monitoring was continuous during the first two hours, then every six hours during the first two days and once every 24 hours thereafter. Areas of activity were calculated by the minimum polygon method (Jennrich and Turner 1969).

Incisions healed completely in five of the six animals, and these individuals were monitored until the signal was lost or to the point of calculated maximum battery life. The incision on the sixth animal abscessed around the 10th day due apparently to improper suturing and the transmitter was removed. When monitoring terminated, the transmitters were removed, the incisions closed, and the animals released.

All six toads undertook initial movements of 12 - 205 m within 24 h, usually during the first 2 h of darkness. The movement was generally unidirectional with one or two shifts of 10-30°. Five of the six toads then established a small activity area of 1 - 64 m^2 (mean = 20.5 m^2, S.E. = 9.7, Table 1.). Three of these five toads remained in the activity area throughout the monitoring period. Two toads (#030, #347) undertook second unidirectional movements of 273 and 165 m seven days later, and established a new area of activity. The sixth toad (#004), made a series of circular movements within an area of 303 m^2 centered around the point of capture. The habitat of toad #004 was along a vegetated rocky bluff overlooking Lake Superior and differed from the wooded terrain of the other five toads. Because of the locality and comparatively large area traversed by toad #004, it was not included in calculations of mean activity area.

It is difficult to assess the total behavioral or physiological effect of the transmitter on the animal. Due to the looseness of the skin, the transmitter was not visible and did not protrude against the skin. Transmitters were removed from four of the six animals at the end of monitoring and all four individuals appeared healthy and had not lost weight. The distances of movement suggest little effect, but there are no valid comparative data.

COPING WITH DEHYDRATION OF TRAPPED TERRESTRIAL ANURANS

One convenient way of sampling terrestrial anurans is to capture them in funnel traps placed alongside a drift fence (Campbell and Christman 1982; Clawson et al. 1984). Depending on how often the traps are checked, it is possible that a captured amphibian would dehydrate and die inside the trap. One way to minimize such mortality is to provide shade by placing forest litter on top of the funnel traps. Still, if the trap lines are not checked at frequent intervals, mortality is a strong possibility.

A study of a wood frog (*Rana sylvatica*) population in a mixed woodland habitat (dominated by *Acer rubrum* and *Betula populifolia*) near Trois-Rivières, Québec (46° 20' N 72° 34' E), was conducted in April 1991. Air temperature averaged ca. 10°C during the study. Drift fences were positioned so as to intercept frogs in their movements to a temporary pool.

The traps were checked and emptied daily at 0900, 1500, and 2100 h. During each trap visit, litter and top soil of the surrounding forest was placed on the sides and top of the traps, and drenched with water. Despite these measures, many specimens died or exhibited signs of dehydration.

For the next three days of trapping, I placed a piece of commercial multi-purpose sponge (ca. 10 x 5 x 7 cm) soaked with pond water in each funnel trap. Sponges remained moist for ca. 48 h after initial soaking, despite generally clear, sunny conditions. During the 72 h period in which sponges were used, I saw no evidence of thermal stress or dehydration in captured frogs. In one trap particularly exposed to the sun, I observed a frog with its urostyle surface in contact with the sponge. Roth (1973) and Christensen (1974) showed that the ventral pelvic integument is more vascularized in terrestrial than in semiaquatic anurans. Presumably, this difference facilitates the uptake of water from the substrate by terrestrial species.

Prepublication Announcement

REPRODUCTIVE CYCLES IN LIZARDS AND SNAKES

Henry S. Fitch

A limited second printing of this long out-of-print classic is being offered at a special pre-publication price. Fitch's book, originally issued in 1970, is the standard compendium and reference worldwide to reproductive cycles, egg clutches and litter sizes, and incubation periods for worm-lizards, lizards, and snakes. Information for this book was accumulated through decades of direct observation and detailed literature search, and represents a wealth of information available nowhere else. In addition to species accounts, which make up the major portion, this book contains sections on factors affecting reproductive cycles, brood sizes, timing of breeding season, and a discussion of viviparity versus oviparity. The concluding Literature Cited, with over 525 references, is an excellent survey of the subject. 247 pages. ISBN 0–89338–037–7.

Prepublication price *$19.95*
After October 15, 1991 *$29.95*

Please add $2.00 postage & handling for the first copy, $.50 for each additional copy. For Kansas delivery add 5.25% sales tax.

HERPETOLOGICAL HUSBANDRY

HUSBANDRY AND PROPAGATION OF THE RADDE'S VIPER *Vipera raddei raddei* BOETT

The Radde's viper *(Vipera raddei raddei)* is found in Armenia and the Nakhichevan region of the Soviet Union, as well as adjacent parts of Turkey and northwestern Iran. The species is included in the Red Data Book of the IUCN and the USSR. Information on the habitat and ecology of *V. r. raddei* in Armenia has been published (Bozhansky and Kudrjavtsev 1986).

Limited success has been achieved in the captive breeding of this species in the Soviet Union. Successful breeding occurred at the Laboratory of the Institute of Zoology of the Academy of Science of Armenia (Agasyan 1985) and the Khar'kov Zoo (Strelkov 1986a, b). General information on the breeding of Radde's viper in the USSR will soon be available (Kudrjavtsev and Mamet, in press).

METHODS

In recent years the snakes were maintained separately in terrariums measuring 70 X 60 X 60 cm. For mating they were placed together in a larger terrarium (140 X 60 X 60 cm), with a 10-12 mm thick substrate of fine gravel, and shelters of pieces of bark or plywood. Some bigger rocks were placed in the cage to assist shedding. The temperature was maintained at 25-32°C, under the heater about 35°C, depending on room temperature. A humidity chamber with moist sphagnum was placed in the cool corner. In the fall, during preparation for artificial hibernation, temperature at night occasionally dropped to 18° C. Food consisted of laboratory mice, with vitamins added as necessary: B-complex (0.4-0.8 ml/kg), sometimes Nutrobal (Vetark Products Ltd.). On rare occasions the largest specimens accepted young chickens. Artificial hibernation usually lasted from early November until February (in 1989-1990: from 1 November until 1 February); specimens were maintained at 10-12°C.

The loss of weight in snakes during hibernation ranged between 0.5 and 4% of their original weight (no correlation between the sex and weight loss was observed). All snakes fed the day after emergence from hibernation. In the group of four snakes (two males and two females), 1990 matings after hibernation were recorded as follows: male #1 and female #1 – 27 February; male #2 and female #1 – 4 March; and male #1 and female #2 – 10 March. These matings were followed by periods of heavy feeding. The females refused food as follows: female #1 – 28 March, female #2 – 4 April. Female #1 gave birth on 3 June to one live young (TL – 243 mm, SVL – 223 mm; mass – 9.96 g) and three infertile masses. Female #2 gave birth on 27 May to three young (TL – 249 mm, SVL – 228 mm; TL – 218 mm, SVL – 200 mm; TL – 233 mm, SVL – 210 mm; and masses – 10.36 g, 8.26 g and 9.06 g, respectively) and two infertile masses.

The young discarded the membranes in which they had been born within the first hours after birth. The first shedding took place during the first eight days of life. After the first shed two young started feeding on newborn mice; the other two refused food, and have consequently been force-fed, using newborn mice.

All four young snakes survived and as of 14 January 1991 measured as follows: TL – 287 mm, SVL – 265 mm, mass – 17.00 g (born to female #1; TL – 365 mm, SVL – 335 mm, mass – 25.30 g; TL – 226 mm, SVL – 210 mm, mass – 7.75 g; TL – 257 mm, SVL – 235 mm, mass – 9.75 g (born to female #2). All the young are listed in the same order as above, the two latter animals being those force-fed.

ANURA

PHRYNOHYAS HEBES (NCN). **FEEDING.** Although largely feeding on invertebrates, occasionally frogs prey on representatives from all vertebrate classes. Here we report on the hylid frog, *Phrynohyas hebes*, feeding on a bat in the Pantanal (Santa Inês Ranch, Poconé, Mato Grosso, southwestern Brasil), on 30 May 1989. This frog is sometimes referred to as *P. venulosa* or *P. v. hebes* (Lutz 1973. Brazilian Species of *Hyla*. Univ. Texas Press, Austin, 260 pp.). The frog, an adult female (85.2 mm SVL), was found inactive at ca. 1500 h under the cover of a water-filled reservoir (500 l), ca. 2 m above ground. Shortly after collection the frog regurgitated a bolus of hair, bones, and a complete skull of the vespertilionid bat, *Myotis nigricans*.

In the Pantanal *P. hebes* shelters in tree cavities and crevices (pers. obs.), and probably the frogs share these shelters with bats. This habit would enhance the possibility of small bats being preyed on by *P. hebes*. Identifications of the frog and the bat were verified by I. Sazima. The frog is deposited in the Universidade Estadual de Campinas, São Paulo, Brasil (ZUEC 9001).

We thank C. F. B. Haddad for reading this note, and O. Cid for facilities at the Santa Inês Ranch.

TESTUDINES

APALONE SPINIFERA SPINIFERA (Eastern Spiny Softshell). **PATTERN DIMORPHISM.** Although it is well known that sexual dimorphism in carapacial pattern occurs in adult *A. s. spinifera* (Ernst and Barbour 1972. Turtles of the United States, Univ. Kentucky Press, Lexington, 347 pp.), the timing of the onset of these pattern differences is apparently unknown. The typical juvenile pattern of large, thick-bordered black carapacial ocelli is replaced in females as growth proceeds by a blotched pattern of lichen-like figures (Webb 1962. Univ. Kansas Publ. Mus. Nat. Hist. 13:429-611). Webb also indicated that one preserved *A. s. aspera* hatchling (PL = 3.5 cm) he examined had a blotched pattern; and the largest females that did not show any evidence of mottling were two *aspera* having PL = 7.6 and 8.0 cm.

Figure 1. Carapacial pattern in three young *Apalone s. spinifera*. Lower left specimen (CL = 56.4 mm) shows smudgy halos while lower right individual (CL = 77.2 mm) shows the mottling which develops subsequently in juvenile females. Upper left specimen (CL = 60.7 mm) demonstrates the typical hatchling/male pattern.

During the course of life history studies of *A. s. spinifera* in the vicinity of the Lamoille River, Chittenden County, Vermont in 1990, I examined about 60 live hatchlings and did not note a blotched pattern on any of them, i.e., they all had the typical juvenile pattern of ocelli. However, in connection with a subsequent experimental headstart (captive rearing for release) program, I observed six *spinifera* for nearly four months posthatching. All were fed a diet of chopped earthworms, live brine shrimp, bits of scallop meat, pieces of raw shrimp, and small freeze-dried *Euphausia pacifica* (Pacific plankton, Wardley's™). Mean dimensions (in mm, ranges in parentheses) of these six young at hatching were CL = 39.4 (37.7 - 40.8) and PL = 28.4 (26.9 - 29.3). Average live mass was 7.53 g (6.70 - 8.71).

Two of the six individuals developed the blotched pattern typical of females. The first indication of mottling (the development of a smudgy halo around each ocellus) was noted when these two young had attained a CL of roughly 52 mm and a PL of ca. 36 mm (see lower left specimen, Fig. 1). As growth proceeded, the dark pigmentation spread out to eventually produce the mottled pattern evident in the largest specimen shown in Fig. 1. The acquisition of the blotched pattern in very young females is obviously not correlated with attainment of sexual maturity (Webb op. cit.). The development of such early color/pattern dimorphism is surprising and represents another unusual facet in the ontogeny of *Apalone*, perhaps in some way related to the genetic control of sex determination in this genus (Vogt and Bull 1982. Copeia 1982(3):699-700).

This project was funded by the State of Vermont as a cooperative venture between the Nongame & Natural Heritage Program, Vermont Fish & Wildlife Department and Wetlands & Wildlife Associates.

CARETTA CARETTA (Loggerhead). **PREDATION.** The anterior region of a *Galeocerdo cuvieri* (tiger shark) washed ashore on Georgia's St. Catherine's Island on July 26, 1990. The intact region measured 122 cm from anterior tip to just posterior of the gills, and the diameter of the jaws exceeded 55 cm. Using these measurements, the shark's length was estimated to be approximately 5 m. Stomach contents included two specimens of *Callinectes sapidus* (blue crab), one unidentified shark, feathers and beak of one *Pelecanus occidentalis* (brown pelican), and the intact carcass of a *Caretta caretta* (loggerhead). The carapace of the turtle was 47.50 cm long and 49.50 cm wide (curved measurement).

Shark predation of sea turtles is common but difficult to document. Dodd (1988. U.S. Fish and Wildl. Serv. Biol. Rep. 88(14):110 pp.) lists eight occurrences of *Galeocerdo* predation on *Caretta* worldwide. This discovery is the first documentation of such predation in Georgia waters.

CLEMMYS INSCULPTA (Wood Turtle). **CLEANING SYMBIOSIS**. Mutualistic relationships in which one species cleans algae or ectoparasites from another are well known between fishes, and between reef fishes and sea turtles. J. Brockmann (pers. comm.) has seen freshwater fishes nibbling at large, stationary, algae-covered *Pseudemys* turtles in Silver Springs, Florida, but the turtles were evidently not presenting themselves to the fishes and simply resembled lumps of algae-covered substrate. There are several reports of freshwater turtles eating algae or skin from other individuals (Lotze 1963. Aquarien Terr. 16:220-221; Meshaka 1988. Herpetol. Rev. 19:88; Moll and Legler 1971. Bull. Los Angeles Co. Mus. Nat. Hist. Sci. 11:1-102).

In May and June of 1985 and 1986 in a creek in Centre County, Pennsylvania, I observed blacknose dace (Cyprinidae, *Rhinicthys atratulus*) apparently cleaning wood turtles on three occasions, and three times saw a turtle apparently unsuccessfully soliciting cleaning. On the three former occasions male turtles were observed in water 18-30 cm deep holding unusually still or moving very slowly. The neck was extended, and often one or more of the legs was extended out to the side in atypical fashion. Small schools of 3-6 dace, 5-7 cm long, darted at the head, neck, and outstretched legs, and could sometimes be seen nipping at the skin. On one of these occasions the turtle picked something off the creek bottom in his jaws, and the fish nibbled at it right from his mouth. On three other occasions another male behaved similarly, keeping motionless or moving very slowly for up to 1.5 h, with neck and legs outstretched, but I could not detect any fish closer than 5-7 cm to him.

Two of the cleaning episodes and one of the apparently unsuccessful ones occurred in a 5 m stretch of one pool. The three other episodes were each in a different location. This behavior may be more common than these few observations suggest. It was difficult to make these observations because of poor visibility underwater, and because the fish were extremely wary, easily disturbed by my presence, and dashed away each time the turtle moved.

GEOCHELONE DENTICULATA (Yellowfoot Tortoise). **MAXIMUM SIZE**. The reported maximum size for *G. denticulata* is 82.0 cm for males and 70.8 cm for females (Pritchard and Trebbau 1984. The Turtles of Venezuela, SSAR, 403 pp.). Here we report on a record size female specimen from the Zoo of the Museu Paraense Emilio Goeldi, Belem, Para, Brazil. The specimen was obtained from a private individual from Porto Velho, Rondonia, Brazil. No other information regarding its origin is available. The specimen is very dark in color with a pronounced flaring of the carapace over the hind legs and pronounced nuchal indentation.

Straight-line CL = 73.1 cm; maximum straight-line length (measured from midline at the rear of the carapace to the anteriormost edge of the carapace) = 75.9 cm; CW (at the level of the 6th marginal scute) = 45.2 cm; PL = 61.5 cm; maximum shell height = 33.0 cm; mass = 57.7 kg.

We wish to thank Antonio Messias Costa and Antonio Carlos Lobo Soares of the Goeldi Museum for their help, and the Rockefeller Foundation (International Partnerships Among Museums Program, AAM) for financial support.

CROCODYLIA

CROCODYLUS ACUTUS (American Crocodile). **REPRODUCTION**. We report here the presence of a double-yolked egg, found in a *Crocodylus acutus* nest at the mouth of the Cuitzmala River, Jalisco, México, on 25 April 1991. The nest contained 27 eggs (mean size 78.3 X 43.7 mm, 91.2 g). Egg fertility in the clutch was 81.5%. The double-yolked egg was infertile, larger and heavier (79.4 X 43.6 mm, 94.4 g) than the mean; it was laid at the end of the oviposition. Presence of twin eggs and large eggs containing two embryos in *C. acutus* has been mentioned by Thorbjarnarson (1989. IUCN Publ. New Ser. CSG-SSC:228-259). Double-yolked eggs of *Alligator mississippiensis* are large, infertile, and laid at the beginning and end of oviposition (Ferguson and Joanen 1983. J. Zool. 200:143-177).

LACERTILIA

CNEMIDOPHORUS UNIPARENS (Desert Grassland Whiptail). **BEHAVIOR**. Various aspects of the behavior of the parthenogenetic whiptail *Cnemidophorus uniparens* have been described for captive populations (e.g, Crews and Fitzgerald 1980. Proc. Natl. Acad. Sci. 77:499-502; Moore et al. 1985. Anim. Behav. 33:284-289; Crews et al. 1986. Proc. Natl. Acad. Sci. 83:9547-9550). These and other studies show that agonistic behavior precedes pseudocopulation in parthenogenetic whiptails (e.g., *C. tesselatus*, *C. velox*, and *C. uniparens*, Crews and Fitzgerald op. cit.; *C. laredoensis*, Paulissen and Walker 1989. Southwest. Nat. 34:296-298). Confirmation of these behaviors in natural populations, however, has not been forthcoming. Agonistic behavior in wild whiptails was not reported in Mitchell (1979. Can. J. Zool. 57:1487-1499) as implied in Crews et al. (1983. *In* R. B. Huey et al, eds., Lizard Ecology, Harvard Univ. Press, Cambridge, Massachusetts, pp. 205-231). Paulissen and Walker (op. cit.) stated that pseudocopulation may be an abnormal artifact of cage conditions and it is "not part of the reproductive biology of parthenogenetic *Cnemidophorus* in natural conditions."

Bouts of pseudocopulatory behavior in whiptails begin with aggressive chases and head bobbing (Crews and Fitzgerald op. cit.). Because no other role has been ascribed to intraspecific agonistic behavior in these lizards, its occurrence in natural populations may represent initial stages of a pseudocopulatory bout. On 26 May 1975 I observed such behavior in adult *C. uniparens* in desert grassland habitat, 32 km SE Willcox, Cochise County, Arizona on the southern slope of the Dos Cabezas bajada. One female was initially observed to run from under a mesquite, then turn and face the area from which she came. At the base of the tree was another female bobbing her head, apparently with an open mouth. She chased the original female for approximately 15-25 cm whereupon the original female retreated a similar distance, each time turning and facing the aggressive female. This was observed on three occasions over a 30 s period. The original female attempted to circle around the base of the mesquite, whereupon she was chased away by the female on the other side. The original female then walked away bobbing her head. She then engaged in nervous foraging behavior. After her last chase the aggressive female under the mesquite began head bobbing and elevated a front foot (armwave). She,

too, subsequently engaged in foraging behavior. Physical contact was not made during the 7 min of observation. A similar series of observations was made on 11 June 1975 in the same area.

Crews et al. (1983. op. cit.) listed the following components of agonistic behavior in captive *C. uniparens*: armwaving, head nodding, bobbing, chasing, biting, aggressive gape, tail flick, face-off, tug-of-war over food, chain biting, and egg eating. All but the tail flick and those requiring physical contact were confirmed for the encounter I observed. The similarities between captive and field observations are not unexpected because most, if not all, of the captives in Crews et al. (1983. op. cit.) were from Cochise County, Arizona.

If the behaviors I observed were initial phases of pseudocopulation, then this behavior is not limited to captive populations of *C. uniparens* as Paulissen and Walker (1989. op. cit.) suggested. I did not observe pseudocopulation, therefore its occurrence in natural populations remains to be confirmed. Such behavior has been described for a natural population of the parthenogenetic *Lepidodactylus lugubris* (McCoid and Hensley 1991. Herpetol. Rev. 22:8-9).

Submitted by **JOSEPH C. MITCHELL**, Dept. of Biology, University of Richmond, Richmond, Virginia 23173, USA

SCELOPORUS VARIABILIS VARIABILIS (Rose-Bellied Lizard). **CANNIBALISM**. In July 1990, we collected an adult male *Sceloporus variabilis variabilis* (MZFC 04829: 59.0 mm SVL 118 mm TL) 1 km NE of Huehuetla, Hidalgo, México. Its stomach contained a hymenopteran (Formicidae) and a hatchling *S. v. variabilis* (18.5 mm SVL, 48.6 mm TL). The head of the hatchling had been crushed, but its jawbone and body were intact, and its tail had been broken into five fragments. This record extends the number of species of *Sceloporus* exhibiting cannibalism to eight. Cannibalism has previously been documented in *S. graciosus* (Knowlton 1934. J. Econ. Ent. 27(5):1001), *S. occidentalis* (Johnson 1965. Herpetologica 21(2):115-116), *S. chrysostictus* (Smith and Fritts 1969. J. Herpetol. 3(3-4):182-183), *S. undulatus* (Groves 1971. J. Herpetol. 5(3-4):205), *S. woodi* (Bowie 1973. J. Herpetol. 7(3):318), *S. magister* (Tanner and Krogh 1973. Great Basin Nat. 33(3):133-146; Vitt and Ohmart 1974. Herpetologica 30(4):413), and *S. torquatus* (Staton and Conzelmann 1975. Southwest Nat. 20(1):147-148).

Smith and Fritts (1969. J. Herpetol. 3(3-4):182-183) suggest that cannibalism of hatchlings can be accidental, but we believe that the present observation of hatchling ingestion in *S. v. variabilis* was deliberate. Two of us (FMQ, MMM) previously observed aggressive behavior from an adult male *S. grammicus* toward a conspecific hatchling. The adult caught the head of the hatchling and killed it but did not eat the smaller lizard. It is possible that cannibalism occurs more often in *Sceloporus* than has been recorded.

We would like to give special thanks to Arturo Gonzalez A., Jack Sites, Jr., and Irene Goyenechea M. for their comments on this manuscript and their assistance with the field work. H. M. Smith and R. R. Montanucci provided helpful information, and Hugo Ponce identified the insect. Funded by the Dirección General de Apoyo al Personal Académico (DGAPA) project IN201789.

SCINCELLA LATERALIS (Ground Skink). **PREDATION**. While many North American raptors commonly feed on small reptiles, reports of predation on reptiles by passerine birds other than corvids and shrikes (*Lanius*) are uncommon (Ross 1989. Amphibians and Reptiles in the Diets of North American Raptors. Wisconsin Endangered Species Report No. 59). Most published reports of small passerines feeding upon reptiles represent isolated incidents (e.g., Browning 1973. Chat 37(4):107).

During May and early June 1990, a pair of eastern bluebirds (*Sialia sialis*) that had nested in a man-made box in a rural yard surrounded by beech-dominated hardwoods (North Carolina, Chowan Co, 7.2 km SE center of Edenton) were observed feeding adult ground skinks (*Scincella lateralis*) to their young. This behavior was first observed on 25 May and at least 12-18 times during the next several days. Both parent birds brought skinks, and would usually shake them vigorously and beat them against the substrate to kill or stun them before feeding them to the young birds (see Fig. 1). One such sequence was recorded on videotape by M. L. Dunn and T. E. Howard.

Scincella are quite common in the area and obviously were a preferred food item for at least this pair of bluebirds. If the behavior of this pair of birds is at all typical, then passerine birds may be more important predators upon ground skinks and other small reptiles than is generally believed.

Figure 1. Predation on *Scincella lateralis* by eastern bluebird (*Sialia sialis*).

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural History, Box 27467, Raleigh, North Carolina 27611, USA and **PARIS R. TRAIL**, Rt. 4, Box 268-A, Edenton, North Carolina 27932, USA

VARANUS PRASINUS BECCARII (NCN). **BEHAVIOR**. An adult female *V. p. beccarii* (SVL = 286 mm, TL = 797 mm, mass = 237.5 g) displayed pre-oviposition and post-oviposition nest guarding aggression. Approximately one week prior to oviposition the female exhibited aggression towards keeper staff who were checking the nestbox for egg deposition. This aggression consisted of lunging, biting, tail slapping, and gular inflation.

On 16 January 1991 the female deposited four eggs in a sphagnum-filled nestbox attached to the side of the enclosure. Immediately the eggs were removed and she again showed aggression, but was not greatly persistent (likely due to physical exhaustion after egg laying). Two days following egg deposition, the adult male was reintroduced into the enclosure. The female immediately pursued the male, and began to bite him vigorously on the back. He attempted to escape by running and climbing, but was again cornered and attacked. At this time the male assumed a defensive posture by hiding his head beneath his foreleg, and compressing his body dorso-ventrally so that he was flat against the substrate. (It is interesting to note that the defensive posturing of the male differed greatly from the commonly observed threat posture of lateral body compression, tail coiling, and gular inflation.) The female, no longer able to effec-

tively bite him on the back, moved to his pelvic region where she could get a relatively secure grip. The male eventually escaped, and found seclusion in a hollow log. He was subsequently transferred into a separate enclosure.

On 1 April 1991 the male was again introduced into the enclosure with the female. The female was persistent in guarding the entrance of the next box, but did not aggressively pursue the male.

Female aggression before and after egg deposition has been observed in other captive groups of *V. prasinus* (J. Branham, pers. comm.). Although little is known of reproductive behavior of this species under natural conditions, we postulate that this behavior is inherent, and not an artifact of the captive environment.

SERPENTES

CHONDROPYTHON VIRIDIS (Green Tree Python). **COMBAT FATALITY**. Numerous accounts of combat behavior between male snakes have been recorded. However, no record exists of the combat behavior leading to the death of one of the participants. Four animals (2 males, 2 females) were housed together in an enclosure measuring 90 X 90 X 150 cm. Numerous branches were available so no two snakes had to share the same branch. The snakes were misted daily. On 2 May 1990, the two males were observed in combat. The combat behavior resulted in moderately severe lacerations to both individuals. They were promptly removed from the enclosure, the lacerations were sutured, and they were housed individually. The suture were removed on 21 June 1990. The lacerations had healed with no infection noted.

On 7 September 1990, they were reintroduced to the previously described enclosure housing the females. On 2, 10, and 11 November 1990 the males were again engaged in combat. They were allowed to remain together this time, with the hopes that the dominant specimen would breed with females. On the morning of 12 November 1990 the males were observed coiled around each other on the enclosure floor. Closer inspection revealed that one of the animals was dead.

The gross necropsy of this animal revealed numerous lacerations on the skin as well as a ca. 15 cm long hemorrhagic area along the neck. Examination by a pathologist determined that there was no evidence of preexisting disease in this snake. Trauma was indicated as the most likely cause of death.

Submitted by **JANICE PERRY-RICHARDSON**, Audubon Park and Zoological Garden, PO Box 4327, New Orleans, Louisiana 70178, USA ●

CROTALUS ENYO CERRALVENSIS (Cerralvo Island Rattlesnake). **BEHAVIOR**. On 24 June 1989 at ca. 0115 h, in Arroyo Viejos, southwest end of Isla Cerralvo, Baja California, México, an adult *Crotalus enyo cerralvensis* was observed ca. 1.5 m above the substrate in a bush (*Pithecellobium confine*). The snake was observed as it exited the plant, moving easily and rapidly across its surface. The snake was followed over a distance of ca. 10 m and during this time it was observed ascending the lower branches of additional shrubs, eventually taking refuge in the crotch of a small bush. In contrast to *Crotalus enyo* on the adjacent mainland, this snake moved rapidly, both on the substrate and in the branches. The presence of this rattlesnake in brush ca. 1.5 m above the substrate suggests that this population may be partially arboreal in its habits.

Rhinocheilus lecontei etheridgei, another subspecies endemic to this island, also displays arboreal tendencies, having been observed in trees ca. 2 m above ground (Grismer 1990. Proc. San Diego Soc. Nat. Hist. 4:1-7). This behavior may be linked to predation on birds or the lizard, *Sator grandaevus*, which roost in trees and bushes. It is of interest that similar arboreal behavior has been observed in another insular endemic rattlesnake, *Crotalus catalinensis*, of Isla Santa Catalina (Grismer, pers. comm.). These observations highlight the need for additional ecological studies of insular rattlesnakes, as well as other insular taxa.

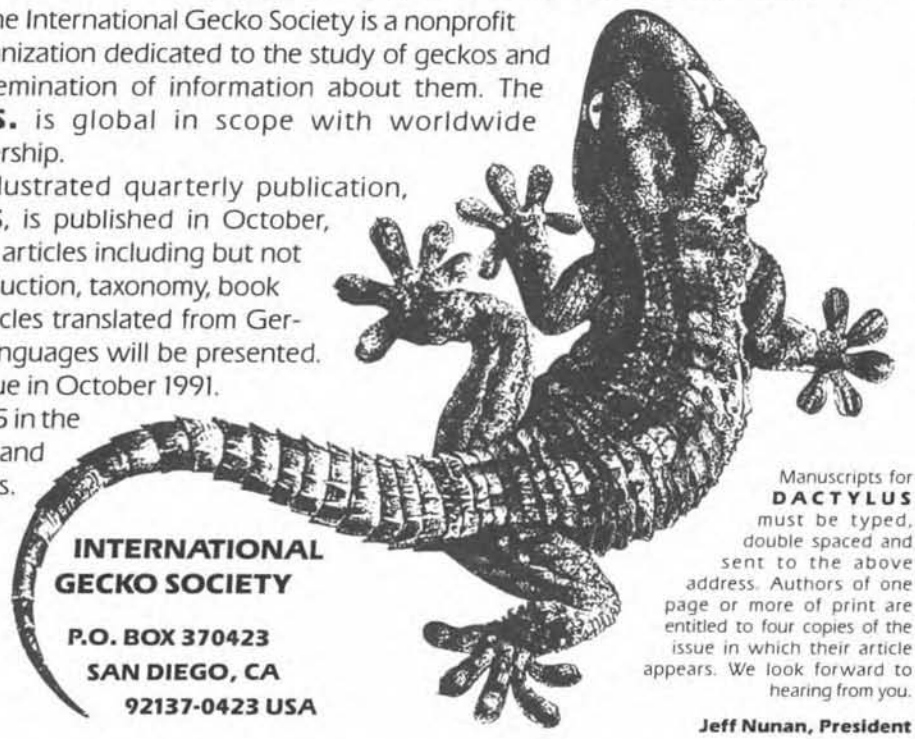
EPICRATES (West Indian Boa). **REPRODUCTIVE LONGEVITY**. Lifetime fecundity of female snakes in a population has the potential for significant effects on individual fitness, abundance, turnover, and other factors relating to population ecology. Although there is some information on snake longevity (see Bowler 1977. SSAR Herpetol. Circ. No. 6, 32 pp.) little data exist on the maximum ages at which snakes reproduce. Four species of *Epicrates* reproduced at the Toledo Zoological Gardens during 1990 at ages approaching or exceeding fifteen years. On 14 September 1990, a female Puerto Rican boa, *E. inornatus* (TZS 833016), imported as an adult prior to 1973 (R. Collins, pers. comm.) gave birth to 11 offspring. On 26 October 1990, a female Jamaican boa, *E. subflavus* (TZS 853002), captive born in 1973 gave birth to 25 offspring. On 2 October 1990, a female Abaco boa, *E. exsul* (TZS 843000), captive born in 1975 gave birth to two offspring. On 2 June 1990, a female Ford's boa, *E. fordi* (PJT 029), captured as an adult near Thomazeau, Haiti in May 1977, gave birth to a single offspring. All the births reported above were the result of captive breedings.

Caution must be used in applying data garnered from captive animals to wild populations. However, the above examples illustrate that at least some species within this genus are physiologically capable of reproduction at an advanced age under certain conditions, and that the potential reproductive value of individual female *Epicrates* within a population may be quite high.

Submitted by **PETER J. TOLSON**, Toledo Zoological Society, 2700 Broadway St., Toledo, Ohio 43609-0110, USA ●



MASTICOPHIS MENTOVARIUS (Neotropical Whipsnake). **REPRODUCTION**. Dates of oviposition and clutch sizes are poorly known for many common neotropical snakes. On 23 March 1991 ca. 5 km S of Tlacotalpan, Veracruz, México, we saw a caracara (*Polyborus plancus*) feeding on a female *Masticophis mentovarius* (ca. 2 m TL). The snake contained 16 eggs averaging about 50 mm long. The eggs had smooth, flabby shells and apparently were not quite ready to be laid. Returning by the same route about 30 min later, a smaller (ca. 1.7 m TL) gravid female of this species was seen about 1 km S of the previous sighting. The posterior half of its body was badly crushed and scavenged. The number of eggs could not be determined accurately, but there appeared to be about 30, slightly more advanced than those of the first snake. The surrounding terrain was marsh and grassland virtually at sea level. Later the same day, a third female *M. mentovarius* (148 cm TL) was collected in sandy coastal hillocks about 11 km E of Alvarado. The posterior part of its body was shrunken and creased; apparently it had very re-

INTERNATIONAL GECKO SOCIETY

The International Gecko Society is a nonprofit organization dedicated to the study of geckos and dissemination of information about them. The **I.G.S.** is global in scope with worldwide membership.

Our illustrated quarterly publication, **DACTYLUS**, is published in October, January, April and July. It features articles including but not limited to: captive care and reproduction, taxonomy, book reviews and historical pieces. Articles translated from German, Chinese, Italian and other languages will be presented. Members will receive their first issue in October 1991.

Annual membership dues are $15 in the USA and $20 for other countries and cover all foreign airmail charges. Please forward all checks and drafts in US currency. Annual membership will begin in October 1991 and includes a subscription to **DACTYLUS**. Membership dues should be sent to:

INTERNATIONAL GECKO SOCIETY

P.O. BOX 370423
SAN DIEGO, CA
92137-0423 USA

Manuscripts for **DACTYLUS** must be typed, double spaced and sent to the above address. Authors of one page or more of print are entitled to four copies of the issue in which their article appears. We look forward to hearing from you.

Jeff Nunan, President

cently deposited a clutch of eggs. Werler (1951. Zoologica 36:37-48) reported a captive specimen from Alvarado laid 17 eggs between March 23 and 25. Alvarez del Toro (1960. Los Reptiles de Chiapas, Instituto Zoologico del Estado, Tuxtla Gutierrez, pp. 156-157) reports that in Chiapas this species lays about 20 eggs in the spring. Our observations agree very closely with theirs.

THAMNOPHIS SIRTALIS FITCHI (Valley Garter Snake). **FEEDING BEHAVIOR**. A small *Thamnophis sirtalis fitchi* was captured from the shallows of a small pond in Douglas Co., Oregon (T.25S., R.1E., Sec. 25, elev. 700 m) on 2 April 1991 at 1655 h. The water temperature was 17.0°C and both air and ground temperature measured 17.2°C. After gentle probing by one of us the snake began to gape and a large larval *Ambystoma gracile* emerged tail-first from its mouth. The snake measured 331.0 mm SVL with a head width of 7.6 mm, and had a mass of 14.8 g (after regurgitating prey). The salamander measured 104 mm TL with a head width of 14.5 mm, and had a mass of 7.1 g. The salamander was alive and survived for 24 h until such time as measurements were made at our laboratory. The salamander had abrasions both on the head's upper surface and along the dorsum of the tail base. Subcutaneous hemorrhaging was present in the abdomen and right lateral area of the head. During handling the salamander died. The snake appeared unharmed and survived. Both animals are currently in the Oregon State University collection.

Other *Thamnophis* have been observed to feed on larval salamanders having a mass equal to 88% of that of the snake (Lind and Welsh 1990. J. Herpetol. 24:104-106). Although both adult and possibly larval *Ambystoma gracile* possess toxic parotid and tail base glands (Brodie and Gibson 1968. Herpetologica 25:187-194), *T. sirtalis* have been observed to consume both larval and adult *A. gracile* in the laboratory with no ill effect (E. D. Brodie, Jr., pers. comm.).

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19: 1–41), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author — curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985(3):802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS

(brief), SUBMITTED BY (give name and address in full — spell out state names — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. All specimen identifications *must* be verified by another authority (not one of the authors). Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to the Section Co-editors, Joseph T. Collins (USA & Canadian records only), Museum of Natural History — Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454, USA, or Darrel Frost (the rest of the world), American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024, USA. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. J. 1980. Geographic Distribution: *Bufo woodhousii fowleri*. Herp. Review 25:198.

CAUDATA

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). USA: TENNESSEE: Putnam Co: pond S jct. of Sheep Bluff Road & Round Cove Road, ca. 5 km W Rt. 70. 10 February 1990. J. H. Roberson. Collected as eggs, reared in laboratory. Verified by B. T. Miller. Middle Tennessee State University (MTSU 42C). County record (Redmond 1985, A biogeographic study of amphibians in Tennessee, Doctoral Diss., Univ. Tennessee, Knoxville, 290 pp.).

Submitted by **JAMES H. ROBERSON**, 2225 East Main Street, Murfreesboro, Tennessee 37130, USA. ●

ANURA

BUFO BRONGERSMAI (Brongersma's Toad). MOROCCO: Prefecture of Marrakech: Skhour-des-Rehamna, 137 km S Casablanca on road to Marrakech (32°30'N, 07°55'W). 29 March 1991. Ignacio De la Riva. Verified by M. García París. Museo Nacional de Ciencias Naturales, Madrid, Spain (MNCN 16616). Second extra-Saharan record; 120 km NE of the initial one reported by Distre et al. (1989, Bull. Soc. Herp. Fr. 51:19–26).

BOOK REVIEWS

Animal Cytogenetics, Volume 4: Chordata 2 Amphibia, by Max King. 1990. Gebruder Borntraeger Verlagshuchhandlung, Johannesstrase 3A, D-7000 Stuttgart 1, West Germany. 242 pp,, 45 figs., 10 tables. DM 198/ US $125. ISBN 3-443-26013-6.

Amphibian cytogenetics is a rapidly developing field of study. New and refined techniques for chromosome preparations have stimulated a large number of investigators to accumulate chromosomal information from gymnophionans, salamanders, frogs, and toads. Most amphibian chromosomes have typically resisted many of the banding techniques which are standard in mammalian cytogenetics but, with new techniques, the barriers are being removed. Morescalchi's (1973) review of amphibian cytogenetics contained fewer than 300 species which has been "the source" for karyological information. King's book, with chromosome references to more than 1000 species and subspecies, is long overdue. Writing such a book is an onerous task because the literature is very scattered in several fields and the systematics and nomenclature in the Amphibia has undergone considerable flux. King has accumulated 32 pages of references and his 37 pages in Appendices 1 and 2 contain a reference for each species as well as documentation concerning those species where information is available on banding, secondary constrictions, nucleolar organizing regions (NORs) or lampbrush configurations. The first half of the text provides a summary of amphibian classification which superimposes the karyotypic information (chromosome numbers and arm numbers) available for each family and subfamily as well as the distribution of the constituent genera. The rest of the text covers more recent information. Comparative banding information illustrates the usefulness of these techniques and there is a good, but short, section on lampbrush chromosomes. A section on the nucleolus organizing region is very comprehensive and draws on information from King's own research in this field. The evolution of genome size, sex chromosomes, and polyploidy are all dealt with in separate sections. The final section on phylogeny is anti-climactic for King only uses chromosome numbers and arm numbers to derive hypothetical trees which are drawn according to Australian custom (upside down!).

PRE-PUBLICATION ANNOUNCEMENT

GENERAL INDEX TO HERPETOLOGICAL REVIEW: 1967-1986 (EXCLUSIVE OF GEOGRAPHIC DISTRIBUTION RECORDS)

Ruth M. Zantzinger, George R. Pisani and Barbara Paschke

The long awaited 20-year cumulative index to *Herpetological Review* (1967-1986) will soon be printed. This volume incorporates the original 10-year index, and will be a valuable reference for locating articles in this diverse periodical. Separate author and taxonomic sections make it easy to use, and a new Obituaries section will aid persons interested in the history of herpetology. This volume will be ca. 88 pages in length, and will be sized 8.5 x 11 inches to match *Herpetological Review's* format. The index is designed to be used in conjunction with the Society's earlier publication, Index to Geographic Distribution Records in *Herpetological Review* (Vols. 1-17) by Ellen Censky.

Order before 1 November 1991, and receive this Index for the pre-publication price of $6, postpaid (US orders only). Non-US orders add postage ($2 surface / $8 air). Order from:

Robert D. Aldridge, Publications Secretary
Dept. of Biology, St. Louis University
St. Louis, Missouri 63103, USA.

If you do not have a copy of Index to Geographic Distribution Records in *Herpetological Review* (Vols. 1-17), why not order it now and have the set? Copies may be ordered from the address above for $5 each, postpaid (US orders only— non-US postage as above, please).

All payments in US funds only.

I found several typographical and nomenclatural errors as well as some errors of fact. Some errors could be rather serious such as placing *Telmatobius montanus* in the genus *Caudiverbera* (pg. 73), not recognizing the synonymy of *Calyptocephalella gayi* and *Caudiverbera caudiverbera*, treating *Pachymedusa dacnicolor* as a ranoid (pg. 67) and considering *Eleutherodactylus* as being a family (pg. 145). King says he uses Frost (1985) as a taxonomic framework but his legend on Table 4 presents a hybrid classification using Frost's as well as Dowling and Duellman's (1978) classification. The factual errors are disturbing. I am particularly concerned about the section on polyploidy. In Table 10, *Xenopus epitropicalis* has 40 (not 36) chromosomes, two hexaploids, *X. boumbaensis* and *X. amieti*, are not included (these would be octoploids if *Xenopus laevis* - like frogs are considered tetraploids). *Bufo danatensis* should have a tetraploid number of 44 and not 88 and the tetraploid, African *Bufo asmarae* (4X = 40) is a synonym for *B.* sp. D and *B.* sp. (*kerinyagae*). *Bufo viridis* has no known natural tetraploid population but this species is listed as being 2X = 22 and 4X = 44. The tetraploid is probably *B. danatensis*. In the polyploid salamander listing, there are no known populations of hybrids involving only *Ambystoma laterale* and *A. tigrinum* as listed in Table 10. The *A. tigrinum* should be *A. texanum*. I do not believe that there is good evidence that either *Astylosternus diadematus* or any of the sirenids are polyploid. King states (pg. 135) that Kawamura (1952) and Moore (1955) used cold shock to induce higher levels of polyploidy in *Hyla versicolor* and then crossed these to *H. chrysoscelis* which gave rise to hexaploids. Tetraploidy in *H. versicolor* was unknown prior to Wasserman's 1970 paper (not 1980 as listed for *H. chrysoscelis* in Table 10) and these crosses were not done in the 1950's. The typographical and factual errors are distracting and could have been corrected with adequate proofreading.

The message that King delivers throughout the text is that amphibian chromosomes are very interesting and important for evolutionary cytogenetics but that there have been few studies that go beyond chromosome morphology (his stage 2 of 10 possible degrees of sophisticated analyses). Much more information from banding techniques and sequence organization is needed and a concerted effort is required in those groups which are under represented. In spite of the drawbacks (and the price of the book), King has produced a very necessary and stimulating treatment of amphibian cytogenetics at a time when this area of study is poised to receive the benefits of new knowledge in DNA technology which involves *in situ* hybridization using selective probes coupled with approaches using immunological techniques and interspecific homologous sequences.

Colour Guide to the Snakes of Sri Lanka, by Anslem De Silva. 1990. R & A Publishing Ltd., 3 Highfield Villas, Newlands Hill, Portishead, Avon, England BS20 9AU, vi + 130 pp., 12 color plates including 69 photographs, 4 maps. Hardcover. £25.00 (approx. $40 U.S.).

This admirable little book is a concise guide to one of the more unusual snake faunas of any country. Of the approximately 80 species of terrestrial snakes in Sri Lanka, about half are endemic to the island. In addition, there are 13 species of sea snakes in its coastal waters. This diversity is substantial for an island only slightly larger than the state of West Virginia (in comparison, the entire United States, about 120 times as large as Sri Lanka has about 115-120 species of snakes). Sri Lanka boasts substantial radiations of typhlopids (10 species), uropeltids (15 species), and colubrids (42 species). De Silva has produced a comprehensive pictorial guide to this remarkable fauna. His work is intended to be a review of existing literature and not a detailed taxonomic or natural history treatment of the Sri Lankan snake fauna. It is successful in this goal. In general, the book is well-produced, although there are a few typographical errors or cases in which dates for references in the text and citation list do not correspond.

Somewhat less than half of the book's 130 pages is devoted to species accounts (57 pages). The remainder of the book consists of a general overview of the Sri Lankan snake fauna (11 pages), an account of man's relationship to snakes in Sri Lanka, including folklore and beliefs (8 pages), snakebite (venomous snakes, snakebite incidence, and indigenous and "western" treatments; 14 pages), keys to families, genera, and species (22 pages), references (11 pages), and an index to scientific names. Four outline maps show topography, climatic and vegetational zones, and political provinces.

The general overview of the snake fauna includes a helpful summary of the geology, climate, rainfall, and vegetation of Sri Lanka, as well as a concise introduction to the relationship of the Sri Lanka fauna to that of India and the Malayan region. Although these introductory accounts are brief, they are extensively referenced so that readers will have ready access to more detailed literature. The discussion of snake folklore provides many fascinating tidbits concerning witchcraft and beliefs about the behavior and coloration of particular species (we learn, for example, that some *Boiga forsteni* are red because of their vampire habits, and that "demon" cobras are thought to be used by certain snake charmers for assassinations). Equally entertaining is the account of traditional methods of snakebite treatment. Although the chapter on snake envenomation discusses the types of venomous snakes, incidence of snakebite, and statistics (age and sex of victims, site of bites, time of bites, etc.), De Silva does not provide an overview of recommended treatments of particular kinds of snakebite in Sri Lanka, nor characteristics of venoms of Sri Lankan snakes or their systemic effects on victims.

Although a chapter is devoted to "man and snakes" in Sri Lanka, De Silva gives us few clues as to how human activities affect snake distributions in Sri Lanka. Given that most of the distributions for species list only a few sites, I was left wondering whether island-wide distributions were truly so scantily documented. Further, what impact is human encroachment and habitat destruction having on the snake fauna? Is there sufficient knowledge to make these assessments?

The core of De Silva's book comprises the keys, species accounts, and color plates. The keys to families, genera, and species are all grouped together, which facilitates moving through them quickly with a specimen in hand. Although the keys are quite useful to have in a volume such as this, the characters used in them rely heavily on some features (e.g., dentition, and even head muscles and braincase structure!) which only the dedicated user will appreciate. None of these features are illustrated. Surely, more user-friendly keys could have been devised. The species accounts are brief, but informative. For each species these give common names (in Sinhala, Tamil, and English), natural history observations, distribution within Sri Lanka, status (commonness or rarity, endemic or not), references, and (sometimes) remarks concerning taxonomy. The natural history sections read much like field guide accounts, with brief statements concerning behavior, reproduction, habitats, diet, size, and distributions. Although knowledge of natural history is, in general, poor for Sri Lankan snakes, the accounts of sea snakes in De Silva's book show how much less is known for these species than for even many of the poorly known terrestrial snakes. The elusiveness of accurately assessing commonness or rarity is illustrated by comparison of contradictory statements for particular species in A. De Silva's Colour Guide and P. H. D. H. De Silva's (1980) treatment of the Sri Lankan fauna.

The addition of two features would have increased the usefulness of the species accounts. Particularly the inclusion of descriptive comments on the species themselves and of distinguishing features from similar species would have allowed greater facility in using this book as an identification guide. Except in the fortunate circumstance of having a specimen at hand represented in one of the color plates, identification of specimens will be impossible without using the keys, which are rather lengthy and involve examination of some features that are difficult or impossible to observe on live specimens, or without the aid of a microscope or dissection. Although brief descriptive comments on coloration and pattern for each species (and particularly of similar species) would have been valuable additions, they would also have lengthened the book substantially given the size of the fauna. Color and pattern descriptions are given in the keys for some species, but not for most. Readers will need to consult other references such as P. H. D. H. De Silva's (1980) larger work for detailed morphological descriptions of the species. Hence, De Silva's book falls a bit uncomfortably between a true field guide and a more technical review. Secondly, the inclusion of a map showing place names would have made the distribution sections of the species accounts (which are mainly lists of towns or villages) easier to interpret for those of us not more intimately acquainted with Sri Lankan geography. Fortunately, De Silva does provide a summary statement for each species about its occurrence in climatic/elevational zones of the country.

The color plates illustrate 53 of the 80 terrestrial snakes of Sri Lanka (a few species are represented by multiple photos), and are a central feature of the book. Most of the plates are from living specimens, although a few are represented by preserved ones (e.g., *Boiga barnesi*, *Liopeltis calamaria*). They are generally good.

These are extremely valuable in illustrating species for which good photographs are difficult or impossible to find in the literature (e.g., 8 of the 15 Sri Lankan species of uropeltids, *Balanophis, Cercaspis, Atretium, Haplocercus*).

The reference list spans the period from 1672 until the late 1980s, and includes most of the classic works on Sri Lankan herpetology and a number of early naturalists' accounts of the island and its people. Hence, it is valuable as a departure point for readers interested in the snake fauna and its natural history, and in the early European exploration of the country.

In summary, De Silva's "Colour Guide to the Snakes of Sri Lanka" is a helpful introduction to this fauna. Although the inclusion of additional descriptive material would have enhanced the usefulness of the book for identifications, the other information about these poorly known animals is well worth having summarized so concisely. I recommend the book to anyone who desires a quick overview of the fauna, an entré into background literature, and a visual feast of a substantial number of these remarkable snakes.

LITERATURE CITED

Michigan Turtles and Lizards: A Field Guide and Pocket Reference, by James H. Harding and J. Alan Holman. 1990. The Michigan State University Cooperative Extension Service, East Lansing, Michigan. 94 pp. Available from: The Michigan State University Museum, East Lansing, Michigan 48824-1045, USA, $8.95 (substantial discount with the purchase of 10 or more copies).

The authors state that this small book is a practical guide for landowners, recreationists, students, educators, wildlife managers, naturalists and others who would like to identify the turtles and lizards of Michigan. In this they have succeeded admirably. It is not a reference book for the professional herpetologist, and should not be judged as such, but instead is a book of keys and illustrations compiled to aid the amateur not familiar with these animals. Only twelve species are covered: two lizards–*Eumeces fasciatus* and *Cnemidophorus sexliniatus*; and ten turtles–*Chelydra serpentina, Sternotherus odoratus, Clemmys guttata, C. insculpta, Terrapene carolina, Emydoidea blandingii, Graptemys geographica, Chrysemys picta, Trachemys scripta* (introduced), and *Apalone* (= *Trionyx*) *spinifera*.

To aid in identification of the turtles, labeled drawings of the shell are included along with a black lateral silhouette of each species. A key, based primarily on pattern and shape of the shell and head follows. While this key is simplistic, it is adequate and errorless. A key identifying the two lizards and separating them from salamanders is next. A glossary of selected terms used in the key and text is included immediately after the keys, but would better have been placed before the keys so that those using it could become familiar with the terminology before using them. Color photographs, for the most part good to excellent, illustrate the carapace, plastron and head of each turtle, and the body and head of the two lizards. Additional color illustrations of eggs, hatchlings, and some behavioral traits (basking, nesting) and a distribution map for each species are also included. The book is well illustrated!

There is a condensed account for each species that includes very brief sections on identification (a description of the reptile), distribution and status within Michigan, habitat, and habits (foods, reproductive biology). A serious reader might wish for more information in these accounts, but what is presented is to the point and accurate, and it was never the purpose of the book to present a complete life history of each species. The book ends with brief sections on conservation, the general biology of turtles and lizards, the study of turtles and lizards, and guidelines to care of turtles and lizards in captivity. A very brief bibliography of the major books on North American or Upper Midwest reptiles closes the book. Unfortunately, the table of contents is too brief and no index is included; the publication would have benefited greatly from both.

The book is paperback with an adequate binding and good quality paper.

Despite the few shortcomings mentioned above, this is a very good book that fills an important niche. More such state reference books for amateurs are needed to build interest in conservation of reptiles and amphibians. My hat is off to the authors for a job well done! I highly recommend this publication for anyone interested in turtles, lizards, or the herpetology of the Upper Midwest.

Frogs and Toads of the Natal Drakensberg, by A. J. L. Lambiris. 1988. University of Natal Press, P.O. Box 375, 3200 Pietermaritzburg, South Africa. x + 62 pp. No price given.

The mountain chain and great escarpment of East Africa is discontinuous; in South Africa the most continuous sharp escarpment and highest mountains are part of the Drakensberg in western Natal and adjacent Lesotho. These cool mountains form a stark contrast to the rest of South Africa; they support the Afromontane vegetation, which consists of heathers mixed with grassland at higher elevations and cool, moist forests at lower elevations. This region is home to a diversity of anuran amphibians, three of which are endemic.

"Frogs and Toads of the Natal Drakensberg" is a paperback field guide 14 x 20.5 cm. Following a preface by John C. Poynton and a brief introduction, the author presents illustrations and definitions of characters used in identifying adults and tadpoles, and a key to the adults. The majority of the pamphlet is devoted to accounts of the 25 species of anurans known from the Drakensberg region. Each account contains a description with illustrations of the hands and feet, comments on habitat and behavior, call and call site, breeding and development with illustrations of tadpoles and their mouths, local range, and comparisons with similar species. Tadpoles of only three species (*Breviceps maculatus, Rana dracomontana,* and *Leptopelis xenodactylus)* are unknown. The pamphlet concludes with three plates of water-color drawings of at least one individual of each species.

For anyone venturing into the precipitous Drakensberg in search of anurans, this pamphlet would be indispensible. The key to adults and illustrations of tadpoles are useful to anyone attempting to identify specimens from the region, and the information on habitat, behavior, breeding, and development will be useful to any worker compiling information on African anurans.

Information for Contributors

The following statement-of-purpose appeared in the Introduction to the first issue of ***Herpetological Review*** in 1967 (Corson Hirschfeld, Editor):

> "*Herpetological Review* incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of individuals, institutions, literature and other components of the field. Perhaps equally important, the *Review* will provide a means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. ***HR*** publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, description of new taxa, or taxonomic revisions are not published in ***HR;*** such material should be submitted to the ***Journal of Herpetology*** (see inside front cover for address).

Manuscripts should be typewritten, double spaced, on 21.5 X 28 cm (8.5 x 11 inch) white paper. Authors are requested to submit four copies of feature article manuscripts. We strongly encourage submissions on a Macintosh disk in Microsoft Word 4.0, although other word processing programs in a Macintosh format (e.g, WordPerfect, MacWrite) are acceptable, as are DOS-formatted disks. Submission by disk will greatly facilitate the review and editing process and reduce the time from submission to publication. Submission on disk must be accompanied by hard copy. Refer to a recent issue of ***HR*** for style and format information. More detailed instructions for submission to Geographic Distribution, Life History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under the appropriate heading.

Submissions for Life History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislative Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Feature articles, newsnotes, and other material should be sent to the Editor. Books for review should be sent directly to the Book Review Section Editor (name and address on inside front cover).

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion. RWH

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi-and non-technical articles (original research should be submitted to the **Journal of Herpetology** - see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letter from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double spaced, on 8.5 X 11 inch paper, and should be sent in duplicate. We encourage submissions on Macintosh disks, though we can also work with TEXT (ASCII) files submitted on 3 1/2" IBM compatible floppies. **Herpetological Review** is composed on a Macintosh SE/30 using Microsoft Word and Aldus PageMaker. Format your documents full-page width; we will fit to **HR** format. Unpublished photographs of an unusual nature or of uncommon amphibians or reptiles may also be submitted. These should be 8 X 10 inch black and white, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled lightly on the back of each print. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs solicited by the Editor will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising. Rates and copy information are available from the Advertising Manager. Fully formatted ads may be provided on 3 1/2 inch disks in several Draw or Paint formats. Contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

HERPETOLOGICAL REVIEW

Volume 22 June 1991 Number 2

SSAR BUSINESS

1992 SSAR MEETING EL PASO, TEXAS

The 1992 annual meeting of the SSAR will be held on the campus of the University of Texas at El Paso (UTEP), 2-6 August. The meeting is being co-hosted by UTEP, El Paso Community College (EPCC), and Sociedad Herpetologica Mexicana.

Currently planned activities include a symposium on amphibian and reptile conservation. Tom R. Johnson is coordinating the symposium. To be considered for participation, please refer to *Herpetological Review* 22(1):2 for directions. Interested persons from Mexico and Central America should contact Oscar Flores Villela, Museo de Zoologia, Fac. de Ciencias UNAM. A.P. 70-399, Mexico D.F. 04510.

Other planned meeting activities include a Mexican food fiesta, social(s), a herp art exhibition, display of local herps, SSAR night at the Juarez Race Track, Mexican shopping tours for partners, and the auction. If enough interest is exhibited, a post-meeting visit to the Chihuahuan Desert Research Institute in Alpine, Texas (and nearby Big Bend National Park) will also be available.

Updates on this meeting will appear in future issues of *Herp. Review*. For further information, contact meeting co-chairmen:

Carl S. Lieb

FARE DISCOUNT FOR SSAR MEETING

Individuals attending the SSAR/HL meeting at Pennsylvania State University in August are eligible for a 5% special meeting discount on Delta excursion flights to either Pittsburgh or Harrisburg. In making reservations with a travel agent or with Delta directly, refer to File Number R29180, to obtain the discount. ●

NEW HR EDITOR

This issue of *Herpetological Review* is the last issue for which I will be serving as the editor. After serving for eight years in this position, one which I have enjoyed immensely, I have decided to "retire" in order to catch up on some long-neglected projects. These have been some of the most exciting and rewarding years of my life and it is with no little regret that I pass the editorial mantle to my successor. As editor, I have had the opportunity to meet and correspond with herpetologists who taught me much, expanded my horizons, and humbled me with their skills and knowledge, whether they were authors or reviewers; I am greatly indebted to these individuals for sharing their wisdom with me.

There are literally hundreds of people — too many to thank individually — who have contributed to *HR* during my tenure as editor and whose advice has been valued and valuable. I extend my gratitude to the authors who have have submitted manuscripts for publication, to the reviewers who shared their expertise and editing skills with me, and to the many SSAR officers, editors, and other members who contributed to *HR* in many ways.

I would particularly like to thank the many people who contributed directly to the publication of each issue of *HR*. These are the section editors and managers, past and present. I would like to recognize these individuals who worked so hard carrying out their own responsibilities:

George Pisani (former editor and managing editor), Tom R. Johnson (artwork), John E. Simmons (past managing editor), Tom Tyning (current managing/desktop editor), Ellen J. Censky and Alvin L. Braswell (past section editors for Geographic Distribution), Joseph T. Collins and Darrel Frost (current section editors for Geographic Distribution), Peter J. Tolson (section editor for Life History Notes), Bern Tryon (section editor for Herpetological Husbandry), Jeffrey Black, Terry Hibbitts, Ray Ashton, and Janice J. Perry (past liaisons for Regional Society News), Steve Hammack (current liaison for Regional Society News), Patricia Riexinger and William S. Brown (past Legislative Alert section editors), Dale R. Jackson, and Kurt A. Buhlmann (current Legislative Alert section editors), Ralph W. Axtell (section editor for Recent Population Changes), Raymond J. Stein (past Advertising Manager), and Elizabeth A. Johnson (current advertising manager).

I would also like to thank those SSAR members who contributed to our recent move to desktop publishing. Without their skill and support, we could not have implemented this technology. These individuals are: Tom Tyning, Robert Hansen, Carole L. Hom, Eric M Rundquist, Christine M. Dwyer, Brian Paulson, Ellen Beltz, Jill Horwich, and Eloise Beltz-Decker. I would like to particularly thank George Pisani, long a stalwart of the Society, for laying the groundwork which was necessary for our move to desktop publishing.

I also acknowledge current and former Society presidents, secretaries, treasurers, directors, and other appointed and elected officials, for their assistance, suggestions, and constructive criticisms.

And now, it is time to introduce **the new editor of *Herpetological Review*.** Robert Hansen of Clovis, California, has, with a surprising degree of alacrity, accepted the yoke of the *HR* editorship, beginning with the next issue. For the past year, Bob has demonstrated his editorial skills by

formatting the Life History Notes for publication. He is a dedicated member of the Society, well respected as a scientist, highly skilled with computer/word processing technology — and eager. I can honestly say that I feel none of the anxiety felt by retiring editors when turning the reins over to their successor. I have full confidence that Bob will serve the Society well as editor of *Herpetological Review*.

All new correspondence regarding *HR* should be sent to Bob at his address (see inside front cover). All "old business" should be sent to me for resolution.

We also welcome the following new section editors: Lyndon A. Mitchell (Herpetological Husbandry), Stephen Corn (Life History Notes), and Aaron M. Bauer (Book Reviews). All correspondence regarding these sections should be sent directly to them (addresses below and on inside front cover of each issue of *HR*).

Finally, I would like to close this very interesting chapter of my life by reprinting a poem which first appeared in the Journal of the Irish Medical Association, 42(247):31-32, 1958:

The Editor's Passport

The Editor stood 'fore the Heavenly Gate,
He bowed before the Man of Fate,
Seeking admission to the fold.
"What have you done," St. Peter asked,
"To gain admission here?"
"I was the Journal's editor, Sir,
For many a weary year."
The Pearly Gates swung open wide
as Peter pressed the bell.
"Come in and choose your harp," he cried;
"You've had your share of hell!"

Good Luck, Bob!!

MJR ●

KUDOS TO OUTGOING HR EDITOR

On behalf of the SSAR, I want to thank Marty Rosenberg for his long-standing effort as editor of *Herp. Review*. Marty's 8+ year tenure ranks as the longest in *HR*'s history (a dubious distinction perhaps!). *HR* is a unique entity among herpetological publications, one that serves a broad community of both amateur and professional herpetologists. Producing such a hybrid publication is a difficult task and we have been fortunate indeed to have someone of Marty's talents and dedication at the helm. It is with no little trepidation that the new editor and staff take over, seeking to maintain the high quality that has characterized the efforts of Marty and his section editors.

I am especially pleased to have coerced Lyndon Mitchell of the Dallas Zoo and Stephen Corn of the U.S. Fish and Wildlife Service to come aboard as section editors for Herpetological Husbandry and Life History Notes, respectively. Further, a new section editorship has been added, that of Book Reviews, to be filled by Aaron Bauer of Villanova University. Correspondence regarding their respective sections should be sent directly to them, as follows:

Lyndon A. Mitchell
Section Editor, Herpetological Husbandry
Department of Reptiles and Amphibians
Dallas Zoo
621 East Clarendon Drive
Dallas, TX 75203, USA

Stephen Corn
Section Editor, Life History Notes
U.S. Fish and Wildlife Service
4512 McMurray Avenue
Fort Collins, CO 80525-3400, USA

Aaron M. Bauer
Section Editor, Book Reviews
Biology Department
Villanova University
Villanova, PA 19085

SYMPOSIUM ANNOUNCEMENT AND CALL FOR PAPERS

The SSAR Conservation Committee is considering sponsoring an Amphibian and Reptile Conservation Symposium at the 1992 annual meeting in El Paso, Texas. Our tentative plan includes a morning session focused on a specific topic such as a taxonomic group (e.g., sea turtles or iguanid lizards), region (e.g., desert, high elevation populations, rain forest), or conservation/management methodology. The committee is interested in co-sponsoring the morning session with persons or organizations involved with the selected topic. The afternoon session would be devoted to a broad spectrum of herpetological conservation and/or management topics. Papers of particular interest are those dealing with "hands on" projects directly related to habitat improvement, mitigation of threats, reproductive enhancement, and restocking or relocation of rare or endangered amphibians and reptiles.

To be considered for participation in the symposium, submit a preliminary abstract by 30 September 1991. Anyone interested in serving as a convener/organizer for the morning session should contact T. Johnson (below) with your ideas.

Final deadline for paper abstracts will be 31 January 1992. Send abstracts or questions to:

Tom R. Johnson, Herpetologist
SSAR Conservation Committee
Missouri Department of Conservation
P.O. Box 180
Jefferson City, MO 65102-0180, USA ●

SSAR TRANSLATION PROJECT

The object of this project is to make available to SSAR members accurate translations of foreign language research articles. Since SSAR has not budgeted money for translation of articles, we must rely on contributions from members. If you have an article that has been translated, please send a copy (or reprint) of the original and the translation to the editor. A few people have volunteered to translate articles, and we are interested in hearing from any others who are willing to contribute their time.

If you have an article for translation that you feel would appeal to a large segment of the herpetological community, send a copy or reprint to the editor and we will try to have it translated. We presently have 181 articles available through the Translation Project. We have also listed articles available from the National Translations Center (NTC) and the National Museum of Natural History (marked SHIS). For copies of the NTC articles write to: NTC, John Crerar Library, 35 West 33rd Street, Chicago, Illinois 60616. For copies of SHIS articles write to SHIS Division of Reptiles and Amphibians, National Museum of Natural History, Washington, DC 20560. For copies of the SSAR translations include 50 cents for postage plus 07 cents per page xerox cost to the editor (address below). The number of pages of original and translation are in parentheses. Previous titles have appeared in *Herpetological Review* 10(3):82-83, 1979; 13(4):111-112, 1982; 16(1):2-3, 1985; 17(2):33-34, 1986. New titles will be published in *Herpetological Review* as they become available.

With this list Robert Aldridge is retiring as Editor of the Translation Project. Requests for titles from this list or any previous list should be addressed to the new Translation Editor:

NEWSNOTES

ROYAL BRITISH COLUMBIA MUSEUM

During 1991 and 1992, the Royal British Columbia Museum will be packing and moving its anthropological, biological, and historical collections to allow for removal of asbestos in the collections buildings. During this time, some of the artifacts and specimens will be inaccessible. The Museum will meet all existing commitments regarding loans and research access and will endeavor to meet any additional requests. The exhibits building will remain open to the public.

For information regarding loans and research, contact Grant W. Hughes, Assistant Director, Collection Program, Royal British Columbia Museum, 675 Belleville Street, Victoria, B.C. V8V 1X4, Canada. (604) 387-5706. ●

EARTHWATCH GRANTS AVAILABLE

Earthwatch, a private non-profit organization that promotes significant scholarship by offering capital, labor, and greater visibility to the scientific community, will award more than 140 grants in 1992. Field grants range from $10,000 to $100,000, with the average grant about $20,000. Funds are contributed by nonspecialist volunteers who participate in the field research.

Preliminary proposals may be made by telephone or by a detailed letter. Upon favorable review, full proposals will be invited for submittal 12 months before the starting date of the project.

For further information, contact: Dee Robbins, Program Director, The Center for Field Research, 680 Mt. Auburn Street, P.O. Box 403, Watertown, MA 02172, USA. (617) 926-8200. ●

FIELD RESEARCH ASSISTANT

A field research assistant in herpetology is needed from January through June, 1992 and 1993 for biodiversity studies in the Philippines. Preference will be given to applicants who are either in or accepted to a graduate program and plan to use this research experience for their dissertation.

Applicants should have extensive field experience and be able to thrive for months in the field. All travel and living expenses will be provided with the applicant's university providing support between the seasons. The position will be awarded in August 1991.

Please send inquiries or a letter of application, resume, and three letters of recommendation to Dr. John W. Ferner, Adjunct Curator of Herpetology, The Cincinnati Museum of Natural History, 1720 Gilbert Avenue, Cincinnati, OH 45202, USA. (606) 344-3374 or (513) 621-3890. ●

NWRA GRANTS

The National Wildlife Rehabilitators Association announces its small grants program. This program makes available two $1,000 research grants in the field of wildlife rehabilitation. Each may be applied to one large project or several smaller research projects each totaling less than $1,000. Applicants must demonstrate financial need and submit a typewritten proposal that includes: name(s) and resume(s) of personnel involved, objectives of the project, a brief description of how the project will be carried out, a brief literature review, and an itemized budget.

An annual report on progress is required. It is expected that those receiving NWRA support will present the results of their projects at an NWRA national meeting within two years of receipt of the grant.

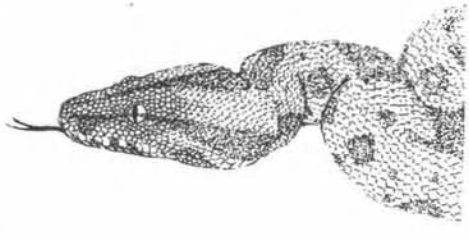
The deadline for submitting proposals for research grants is 15 December of each year. Recipients will be announced at the NWRA annual meeting in February and in writing.

Proposals should be submitted to: Mark Pokras, DVM, Tufts University School of Veterinary Medicine, Wildlife Clinic, 200 Westboro Road, North Grafton, MA 01536, USA. ●

REPOSITORY FOR FROZEN TISSUES

We wish to publicize the existence of the Collection of Frozen Tissues at the LSU Museum of Natural Science. The Collection is supported by NSF and LSU as a service to the research community. It contains tissue samples of over 30,000 vertebrate animals preserved at -70°C.

We are committed to proper curation and research use of frozen tissue samples. Although our freezer space is limited, we would like to offer our collection as a repository for personal research collections or orphaned collections that are no longer needed but are still valuable to the research community, and are perhaps occupying needed freezer space.



Materials donated to the Collection become the property of the Collection (our policy on Collection use is available upon request). If you have materials you wish to donate or would like to use materials in the Collection, please contact Dr. Robert M. Zink, Curator, Collection of Frozen Tissues, Museum of Natural Science, Louisiana State University, Baton Rouge, LA 70803, USA. ●

OPENING FOR WILDLIFE BIOLOGIST

The Division of Fish and Wildlife, Mariana Islands, is soliciting applications for a wildlife biologist. The job description is: Wildlife Biologist II - Herpetologist: Project leader for brown tree snake interdiction and control; Conduct/supervise trapping and search efforts; evaluate quarantine procedures and advise inspectors, shippers, and regulators on means of preventing snake introductions. Assess impacts of other introduced amphibians and reptiles and determine status of native herps as time permits. $23K. Contact ASAP: Arnold I. Palacios, Chief, Division of Fish and Wildlife, CNMI Government, Saipan, MP 96950. Country Code: 670-322-9095 or 9729. FAX 322-3386. ●

REPRINT SALE

The Carnegie Museum of Natural History is conducting an inventory reduction sale of its scientific publications (*Annals*, *Bulletin*, *Special Publications*) printed prior to 1985. A 50% price reduction is offered on research articles in herpetology, ichthyology, mammalogy, invertebrate zoology, anthropology, birds, vertebrate and invertebrate paleontology, and botany. Please write for listings of your choice to: Office of Scientific Publications, The Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, PA 15213-4080, USA. FAX (412) 622-8837. ●

MEETINGS

SYMPOSIUM ON NATURAL HISTORY COLLECTIONS

An International Symposium on the Preservation and Conservation of Natural History Collections will be held 10-15 May 1992 in Madrid, Spain. The symposium will focus on the concerns of the natural history community for the current status and future direction of anthropological, biological, and geological collections in the world.

The first circular is available now and includes an outline of the general program. A preliminary registration form is included. For further information, please contact: Julio Gisbert and Fernando Palacios, Museo Nacional de Ciencias Naturales, Jose Gütierrez Abascal, 2 28006 Madred, SPAIN. FAX: 1/5645078. BITNET: MCNMA13@EMDSIC1. ●

WORLD CONGRESS ON TOXINS

The 10th World Congress on Animal, Plant and Microbial Toxins will be held in Singapore, 3-8 November 1991. (Note - the previously advertised dates of 1-7 July have been changed.) The main theme of the congress will be "Recent Advances in Venom and Toxin Research." The tentative programme consists of eight plenary sessions and lecture sessions on venomous snakes of the world, poisonous and medicinal plants, mycotoxins and phycotoxins, toxic dinoflagellates and red tides, toxin-producing fungi and bacteria, food poisoning, and insects and arthropods. Numerous workshops and symposia are also scheduled.

For further information about and registration forms for this meeting, contact Dr. P. Gopalakrishnakone, Organising Chairman, 10th World Congress I.S.T., c/o Department of Anatomy, Faculty of Medicine, National University of Singapore, Singapore 0511, SINGAPORE. ●

6TH SEH MEETING

The 6th Ordinary General Meeting of the Societas Europaea Herpetologica will be held 19-23 August 1991 at the Hotel

"Agro," 1121 Budapest, Normafa u. 54. The meeting is being organized by the Hungarian Academy of Sciences, section of Biological Sciences, and the Hungarian Natural History Museum. The conference will consist of an invited plenary lecture, oral presentations in two parallel scientific sessions, poster presentations, social events, and post-congress excursions.

Information about and registration forms for this meeting can be obtained in the U.S. by contacting the editor of *Herpetological Review* at tel. (216) 368-3558, or by contacting the SEH Organizing Committee: SEH 6th O.G.M., Zoological Department, Hungarian Natural History Museum, H-1088 Budapest, Baross u. 13., Hungary. Tel. (361) 113-00-35, FAX: (361) 113-88-20. ●

DGHT MEETING

The Deutsche Gesellschaft fur Herpetologie und Terrarienkunde (DGHT) it holding its annual meeting 18-22 Setpember 1991 at the Unionssale, D 5300 Bonn. Members of SSAR are invited to attend and/or participate in this meeting. The congress language is German.

For further information, contact the DGHT, Adenauerailee 150-154, D-5300 Bonn 1, Germany. ●

ASZ ANNUAL MEETING

The 1991 Annual Meeting of the American Society of Zoologists with the American Microscopical Society, Animal Behavior Society, The Crustacean Society, and The International Association of Astacology will be held at the Hyatt Regency Hotel in Atlanta, Georgia, during the traditional post-Christmas period.

A 1 August deadline for receipt of abstracts of papers (oral or poster presentations) has been set. Posters are particularly encouraged.

Thirteen symposia and workshops are currently scheduled, including: Basic Animal Behavior Research in Zoos: A Link with the Wild; Neuropeptides — Synthesis, Release, Action, and Evolution; Development and Evolution of the Vertebrate Head; Strategies for Analyzing Neuropeptide Systems; and Structure, Development, and Phylogeny of Cranial Nerves.

For more information, contact: Mary Adams-Wiley, Executive Officer, American Society of Zoologists, 104 Sirius Circle, Thoasand Oaks, CA 91360. (805) 492-3585. FAX (805) 492-0370. ●

REGIONAL SOCIETIES

ADDRESS CHANGES

The following new societies/address changes have been submitted since the list of herpetological societies was printed in the June 1989 issue of *Herpetological Review*:

Herpetology Online Computer Network
P.O. Box 52261
Philadelphia, PA 19115, USA
ACCESS: (215) 464-3562 via modem

Philadelphia Turtle & Tortoise Club
c/o Mark F. Miller
9573 Walley Avenue
Philadelphia, PA 19115-3009, USA

Society officers are encouraged to forward to the SSAR Regional Society Liaison (see inside front cover of any HR) any address changes for their society. Newly formed societies are invited to announce their existence in this column, and established societies are invited to submit short descriptions of their organization for publication in this column.

CHICAGO HERPETOLOGICAL SOCIETY HERPETOLOGICAL GRANTS

The Chicago Herpetological Society (CHS) has established a program to award financial support for herpetological research, education, and conservation. *CHS Herpetological Grants* compliments the SSAR Grants-in-Herpetology program to provide more funds for herpetological research. Interested parties may apply for a grant in any one of the following categories, but may submit only one application per category per year. Not all categories may receive awards each year. Individual awards will not exceed $500.

1) Herpetology in Illinois. Proposals may address any aspect of herpetology in Illinois.

2) Graduate Student Research in Herpetology.

3) Undergraduate Student Research in Herpetology. Undergraduate and high school student research projects in herpetology for course credit, extra credit, science fairs, and the like should be submitted in this category.

4) Field Studies in Herpetology. Proposals involving travel expenses, survey collections and other fieldwork should be submitted here.

5) Conservation. Proposals involving threatened herpetological species or environments, declining populations, and similar problems are appropriate here.

6) Captive Management, Husbandry, and Propagation.

7) Miscellaneous. This category is for proposals that do not fit nicely into other categories.

Applicants must be dues-paying members of the CHS. The committee reserves the right to reassign the category under which a given proposal is submitted. Recipients of SSAR grants will not be eligible for CHS grants in the same calendar year. In the event that applications are lacking, awards in a given category may be withheld and allocated funds may be reassigned to another category. Recipients of grants are required to submit results of their subsidized work in writing within a reasonable amount of time for publication in the CHS *Bulletin* or elsewhere.

Applications will be similar to those for SSAR grants. Each must include:

1) Background and objectives of the proposal

2) Materials and methods for carrying out the project

3) Budget, not to exceed $500

4) Brief resume of the applicant

5) A letter of support from the most appropriate sponsoring party, such as faculty advisor or committee chairperson, course instructor, or the president of a sponsoring herpetological society.

The application must be typed, double-spaced, and must not exceed five pages, excluding resume and budget. Failure to follow this format may result in an application being rejected. All applications must

be submitted in duplicate and be received no later than 31 August 1991. Awards will be announced by 30 November 1991.

Submit applications or questions to:

Stephen L. Barten, D.V.M.
CHS Herpetological Grants
Vernon Hills Animal Hospital
1260 Butterfield Road
Mundelein, IL 60060
(708) 367-4070, FAX (708) 367-0374

CHS Herpetological Grants are funded primarily by proceeds from book sales. Your tax deductible donation to support this program would increase the amount of awards available while supporting valuable herpetological research. ●

LEGISLATIVE ALERT

This column is produced by the SSAR Conservation Committee to alert members of the herpetological community to recent and proposed regulatory changes involving amphibians and reptiles. We encourage SSAR members to notify us of any significant changes in state, national, or international conservation laws as they relate to these animals. For further details about any of the following, or to report additional changes, please contact Kurt A. Buhlmann, SSAR Conservation Committee, c/o Division of Natural Heritage, Virginia Department of Conservation and Recreation, 203 Governor Street, Suite 402, Richmond, CA 23219, USA.

The following final and/or proposed listings and regulations have been announced by governmental regulatory agencies. Pertinent *Federal Register* (FR) citations are given for U.S. notices.

U.S.: *Crocodylus porosus* (saltwater crocodile); proposal to reclassify all populations of saltwater crocodiles in Australia from endangered to threatened [FR 55(188):39489-39493, 9/27/90]

Populations of the saltwater crocodile in the Northern Territory have undergone significant recovery since protection from hunting in 1972. Analysis of all available monitoring results from 1975 to 1987 show that the density of wild saltwater crocodiles in tidal rivers has tripled since surveying began. Today, the species occupies the whole of their known range in the country. The proposed rule, if made final, would allow for the importation of specimens from ranching operations into the United States. Populations of saltwater crocodiles in other countries would remain in the endangered status.

U.S. *Graptemys flavimaculata* (yellow-blotched map turtle); has been formally listed as threatened [FR 56(9):1459-1463, 1/14/91], [see this column, *HR* 21(4):80, for details]

FLORIDA: *Gopherus polyphemus* (gopher tortoise); incidental take, draft rule (see this column, *HR* 21(4):80, for details.

Proposed rule was defeated by the five commissioners of the Florida Game and Freshwater Fish Commission, 13 January 1991.

NEVADA: The Desert Tortoise Conservation Center, near Las Vegas, opened 16 June 1990. It is the first large-scale research facility established to receive desert tortoises (*Gopherus agassizii*) salvaged from private lands under development. Tortoises from 11 different tracts of private land, totalling 7,200 acres, could be transferred to the center. The Bureau of Land Management (BLM) is in charge of the center. The Nevada Department of Wildlife is supervising the salvaging process (Endangered Species Technical Bulletin, Vol. XV, No. 9, Sept. 1990).

VIRGINIA: New regulations. Effective 15 October 1990 (VR 325-03, Virginia Department of Game and Inland Fisheries), "it shall be lawful to take and possess no more than three individuals of any single species of amphibian or reptile or 20 individuals of any single species of aquatic invertebrates and nongame fish for private use....It shall be lawful to take bullfrogs for private use except from the banks or waters of designated trout waters. The daily limit for bullfrogs shall be 15....It shall be lawful to take snapping turtles, crayfish and hellgramites for sale." Scientific collecting permits are required for all research activities. For more information contact: Virginia Department of Game and Inland Fisheries, 4010 West Broad Street, Box 11104, Richmond, VA 23230.

FEATURES

HABITAT UTILIZATION AND FEEDING HABITS OF *NEUSTICURUS ECPLEOPUS* IN A BRAZILIAN TROPICAL RAINFOREST

Although there are about seven studies that include information about the ecology of the tropical rainforest microteiid lizard *Neusticurus ecpleopus*, most of the reports are anecdotal. In a revision of the genus *Neusticurus*, Uzzel (1966) argued that although these lizards are usually considered to have aquatic tendencies, observations that confirm this are scant. However, Vanzolini (1986) recently argued that all observations on *Neusticurus* species in the field suggest association with rivulets in the forest.

This study reports systematic field observations to evaluate habitat utilization and feeding habits of *Neusticurus ecpleopus*. The field work was carried out at the Igarapé de Bomba d'água, an area of primary tropical rainforest in Serra de Carajás (5°54'S, 49°53'W), Pará, Brazil, between 22 and 26 July 1987. An area of ca. 400 m^2 (26 x 15 m) containing a stream (50-100 cm wide, 5-20 cm depth) with two smaller ramifications (20-30 cm wide, 2-8 cm depth) was demarcated in the forest. At the time of the study, the soil surface of the area had dry leaf litter, except for a 10-35 cm-wide margin to the rivulets and stream, which presented wet litter. The extension of rivulets and stream was measured and summed, giving an estimate of total extension of water course in the area.

During four days, all the litter of the area was systematically stirred looking for lizards. When a lizard was sighted, its original position was recorded and an attempt was made to capture it. The snout-vent length of each captured lizard was measured to the nearest 0.1 mm with calipers. The temperature of the lizard, water, and air (1 cm above soil) were taken to the nearest 0.1°C, using a digital thermometer. After measurements, the lizard was toe clipped and released. A description of the microhabitat (dry or wet litter; in water or on stone) at the original position of the lizard was recorded and the distance from this point to the nearest water course measured. The width and depth of the nearest water course were also recorded. In a similar area more than

Table 1. Number of items, volume (in mm^3) and frequency of each type of prey of *N. eecpleopus* in Serra de Carajás (N=18)

Prey	Number	%	Volume	%	Frequency

Unidentified parts of arthropods	-	-	46.8	8.2	-

200 m away, 18 *N. ecpleopus* were collected and killed for stomach content analysis. In the laboratory the stomach contents were identified to order, counted, and their volume estimated by multiplying their three dimensions (Schoener 1967).

Ninety-seven percent of the lizards were found near or in rivulets narrower than 50 cm and having shallow depth (3-8 cm). The low density of lizards by wider streams may be due to either a higher density of predators or a lower density of prey in these habitats. Most of the lizards (90%, N = 30) captured during the study were 20 cm or closer to a water course. Of these, three (10%) were found in water with belly and limbs submerged and head and dorsum exposed; the others (80%) were on wet litter at the margin. The mean distance between lizards and a water course was 17.1±20.9 cm (N = 30). Only one lizard (3%) was found on dry litter and it was the most distant from water (120 cm). These data agree with Vanzolini's 1986 statement, confirm previous observations (Fitch 1968; Sherbrooke 1975; Dixon and Soini 1975), and suggest that *N. ecpleopus* lives strongly associated with small streams in the forest. Five lizards escaped to shelter located under or between roots of trees at the margins of water courses, and exposed by water drainage.

Only 17% of the lizards captured during the study were adults. The high proportion of juveniles (83%) suggests that recruitment is occurring in the area during July. Sherbrooke (1975) in a study of the reproductive cycle of *N. ecpleopus* at Tingo Maria, Peru, showed that there they breed throughout the year, with seasonal fluctuations in percent of gravid females.

Data on some marked lizards indicated that they frequently return to the same point, probably a foraging site, on consecutive days. Since this lizard is not uniformly distributed in the forest, but associated with small streams, there is probably no biological significance in estimating its density per unit of forest. It is probably more appropriate to estimate its density by unit length of water course.

The data obtained in Serra de Carajás suggested an abundance of one lizard per 4-5 m of rivulet. This can vary with the dimension of the water course, as changes in depth and width of a stream probably are followed by changes in densities of prey and predators of *N. ecpleopus*.

Table 1 shows the number, volume, and frequency of each type of prey of *N. ecpleopus* at Serra de Carajás. Ten different types of prey were classified from the stomachs but most of the volume was composed of adult (20.2%) and larval (10.6%) Coleoptera and larval Diptera (17.2%). The simultaneous occurrence of aquatic (dytiscid coleopterans and aquatic dipteran larvae) and terrestrial prey (collembolans, blattarians, and *Ochaetomyrmex* ants) suggests that this lizard forages both in water and in wet litter.

The mean body temperature of *N. ecpleopus* in the area was 25.5±0.4°C (N = 8). Fitch (1968) found the mean body temperature of 26.8±0.5°C (range = 24.5-30.4°C) for 15 lizards in Santa Cecilia, Ecuador. The low body temperature of *N. ecpleopus*, which is characteristic of non-heliotherm lizards, was positively ($r = 0.63$; $N = 8$; $p > 0.05$), but not significantly, related to air temperature. There was a lower and not significant relationship between water temperature (=20.3°C) and body temperature ($r = 0.32$; $N = 8$; $p > 0.05$), suggesting that air must be the main source of heat for this semi-aquatic lizard.

I conclude that *N. ecpleopus* is a semi-aquatic non-heliotherm lizard strongly associated with rivulets in the forest and that it forages in the water and in the litter at the rivulet margins.

ACKNOWLEDGMENTS

I am grateful to W.W. Benson, I. Sazima, P.S. Oliveira, H.G. Bergallo, C.B.A. Ramos, and C. Strussman who kindly reviewed the manuscript and offered helpful suggestions. This study was supported by a grant N 130673/87 of the Conselho Nacional de Desenvolvimento Científico e Tecnológico.

SOME NOTES ON SEA TURTLES

I. EVIDENCE FOR HAWKSBILL SEA TURTLES BREEDING IN GALAPAGOS ISLANDS

Specimens and records in the British Museum (Natural History) document, evidently for the first time, breeding of the hawksbill sea turtle (*Eretmochelys imbricata*)in the Galapagos. BMNH Nos. 1938.9.4.6-8 are catalogued under *Eretmochelys imbricata* as "eggs found in the Galapagos Islands 11/2/38 laid at 10 PM; T.O.M. Sopwith, Esq., 46 Green Street, W1." Number 80 (T.O.M.S.?) is labelled "22 days after oviposition;" number 81, "32 days after oviposition." Neither of these two embryos shows species-specific characteristics. Number 82, for which there is unfortunately no specimen, is labeled "24/3/38 (i.e. 41 days). This embryo showed definite signs of life for about 10 mins after removal (from the egg). Further specimens showed no further development as the weather became very cold."

A letter in the herpetology files from H.W. Parker to Sopwith, dated 8 November 1938, states "...I have examined the reptiles..." thus indicating that Parker himself had identified the embryos as *E. imbricata*. The collector (Sopwith?) presumably saw the female, for the time of laying is recorded. This species has not been recorded previously as breeding in the Galapagos (Green and Ortiz 1982; Witzell 1983).

Witzell, W.N. 1983. Synopsis of Biological Data on the Hawksbill Turtle *Eretmochelys imbricata*. FAO Fisheries Synopsis No. 137.

II. HAWKSBILL SEA TURTLE IN EGYPTIAN RED SEA

Frazier and Salas (1984) reviewed records of sea turtles in the Egyptian Red Sea, and commented that classic works such as that of Anderson (1898) made no mention of these distinctive animals. However, Anderson did obtain at least one sea turtle, BMNH 97.11.13.4, labeled "Gulf of Suez; Presented by Dr. J. Anderson," is an immature *Eretmochelys imbricata* (curved carapace length = 25 cm) in spirit.

Anderson, J. 1898. Zoology of Egypt. London, Bernard Quaritch.

III. LOGGERHEAD SEA TURTLE FROM THE RED SEA

In reviewing specimens of *Caretta caretta* in the Red Sea, Frazier and Salas (1984) only listed rhamphothacae from Sinai (FSM 39107) and a photograph. A good osteological specimen was omitted; BMNH 1983. 1191, a skull with a total length of 30 cm, is catalogued as "Red Sea." It was transferred to the BM(NH) from the Rothschild collection in Tring, and no further data are known

VIEWPOINT: A NEW TAXONOMIC ARRANGEMENT FOR SOME NORTH AMERICAN AMPHIBIANS AND REPTILES

Subsequent to the discussion by Frost and Hillis (1990) of species and the relevance of species concepts to practical taxonomy, it has become clear to me that a relatively large number of species of amphibians and reptiles in the United States have been camouflaged by the "subspecies" taxonomy that has grown up around what I now think is an out-dated viewpoint.

Besides providing recognition of the real species diversity in nature, a rigorous application of the evolutionary species concept (as discussed in Frost and Hillis, 1990) would also reduce the number of arbitrarily defined subspecies dramatically, although several subspecies complexes (e. g. *Ensatina esch-scholtzii*, *Lampropeltis getula*, *Lampropeltis triangulum*) undoubtedly contain a number of real species. I realize that in some cases the recognition of an obvious species (e. g. *Ensatina e. klauberi* elevated to *E. klauberi*) might leave the residual binomial (i. e. *Ensatina eschscholtzii*) representing a group of cryptic species of uncertain relationship to each other. However, because no changes can be made in these "agglomerative" taxa without some initial uncertainty, I have not addressed them here.

In my opinion, much of the specific and subspecific taxonomy in use by herpetologists today is arbitrary and lacks historical reality. It is also clear that the non-systematist public is generally unaware of this. The following list of "hidden" species is not exhaustive because of the ambiguity of evidence and information available to me. (Is *Pseudemys rubriventris bangsi* morphologically or genetically distinct from *P. r. rubriventris*?

1 *Rana capito* would retain the subspecies *R. c. aesopus* and *R. c. sevosa*. *Rana areolata* would retain the subspecies *R. a. circulosa*. 2 *Arizona occidentalis* would retain the subspecies *A. o. candida*, *A. o. eburnata*, and *A. o. noctivaga*. *Arizona elegans* would retain the subspecies *A. e. philipi*. 3 *Diadophis amabilis* would retain the subspecies *D. a. modestus*, *D. a. occidentalis*, *D. a. pulchellus*, *D. a. similis*, and *D. a. vandenburgii*. *Diadophis punctatus* would retain the subspecies *D. p. amyl*, *D. p. edwardsii*, *D. p. regalis*, and *D. p. stictogenys*. 4 *Pituophis catenifer* would retain the subspecies *P. c. affinis*, *P. c. annectens*, *P. c. deserticola*, *P. c. pumilis*, and *P. c. sayi*. *Pituophis melanoleucus* would retain the subspecies *P. m. lodingi* and *P. m. mugitus*.

If so, it should be *Pseudemys bangsi*.) None-the-less, based on Conant (1975), Conant and Collins (1991), and Stebbins (1985), the following taxa exhibit two characteristics which reveal their specific distinctness: 1) They are mapped as allopatric (based on the best published evidence available), and 2) they are in some way morphologically (and presumably genetically) distinct.

I would encourage the adoption of the taxonomic arrangement listed above, unless or until data indicate differently. Indeed, some systematists have already recommended a number of the changes proposed above (see Collins, 1990). Not to do so continues the myth of morphologically distinct, allopatric subspecies, thereby diluting the species concept and obfuscating the evolutionary diversity of the North American (north of Mexico) herpetofauna.

EVOLUTION OF ECOLOGICAL DIVERSIFICATION IN DESMOGNATHINE SALAMANDERS

The salamander subfamily Desmognathinae, with three genera and 14 species, is restricted to eastern North America. Communities of salamanders throughout much of this region contain a single species of *Desmognathus*, typically a "streamside" form, either *D. fuscus* or an ecological equivalent like *D. apalachicolae*, *D. auriculatus*, or *D. brimleyorum* (e.g., see Means 1975). These streamside species usually have an aquatic larval period of one year or less, generally 8-12 months as in *D. fuscus* (Wilder 1913; Organ 1961a; Danstedt 1975; Juterbock 1990). Following metamorphosis the salamanders live in moist habitats along the edges of streams.

In the southern Appalachian Mountains, particularly the southern Blue Ridge Physiographic Province, additional desmognathine species occur and multispecies communities are the rule. Some of the species in these communities are streamside forms, including *D. monticola, D. ochrophaeus, D. imitator,* and *D. santeetlah.* However, these communities also contain several ecologically specialized species — at one extreme the large, aquatic *D. quadramaculatus* and *Leurognathus marmoratus*, at the other the small, terrestrial *D. aeneus* and *D. wrighti.*

The life histories of the two aquatic species are characterized by lengthy larval periods of two years or more, followed by an aquatic (*L. marmoratus*) or semi-aquatic (*D. quadramaculatus*) mode of life after metamorphosis (Martof 1962; Bruce 1985, 1988). *Desmognathus welteri*, occurring in the western Appalachians, is another large species with a long larval period and semi-aquatic habits after metamorphosis (Juterbock 1984). Its ecology and life history are not as well known as those of other species.

In contrast, the two small, terrestrial species have no free-living aquatic larval stage (Organ 1961b; Harrison 1967). *Desmognathus aeneus* is usually found near seeps, but ranges far into the forest. *Desmognathus wrighti* is essentially a forest dweller, although it congregates in seeps in the colder months.

Communities of desmognathine salamanders in the southern Blue Ridge usually contain three to five species, though in some areas six or even seven species may coexist, e.g., in the Mt. Rogers-Whitetop area of southern Virginia (Organ 1961a) and in the Great Smoky Mountains (Huheey 1966; Tilley et al. 1978; Tilley 1981). A remarkable community of desmognathines occurs in the southern Nantahala Mountains, in the drainage basin of the Nantahala River in southwestern North Carolina, where six species are found: *Leurognathus marmoratus, Desmognathus quadramaculatus, D. monticola, D. ochrophaeus, D. aeneus,* and *D. wrighti.* This is the only documented locality where the two most aquatic species (*L. marmoratus, D. quadramaculatus*) and the two most terrestrial species (*D. aeneus, D. wrighti*) coexist with one another and with the streamside species *D. monticola and D. ochrophaeus.*

Perhaps the most interesting relationship involves *D. aeneus* and *D. wrighti*, which were first reported in sympatry in the region by Tilley and Harrison (1969). Although the latter species is not abundant in the southern Nantahalas, it seems to be present throughout the upper Nantahala River drainage basin at elevations of 1000 m and higher. The degree of habitat overlap has not been quantified for *D. aeneus* and *D. wrighti*, although I have observed them in proximity to one another in forest floor habitats along the Nantahala River at elevations of 1000-1100 m.

Is there anything about the southern Nantahalas which will account for the high diversity of desmognathines? One probable contributing factor is climate. These are the southern-most high mountains of the Appalachians, with a maximum elevation of 1,676 m (5,499 ft) on Standing Indian Mountain. Temperatures are moderate and precipitation is high, in fact the highest in eastern North America (Swift 1987). The long-term (54-year) average precipitation at Mooney Gap (1,364 m elevation) on the Little Tennessee-Nantahala Divide, is 2,362 mm (93 inches) per year. Precipitation is essentially nonseasonal; the driest month is October (161 mm), and the wettest is March (250 mm). This pattern appears to be typical for the southern Nantahalas. Climatic regimes in other areas of high desmognathine diversity in the southern Appalachians are similar, though somewhat cooler and drier.

The virtual restriction of the two most aquatic and two most terrestrial desmognathines to the southern Appalachians, and their coexistence only in the wet, mesothermal environment of the southern Nantahala Mountains, suggests that the evolution of aquatic as well as terrestrial adaptations in the subfamily have been largely confined to moist, stable, montane environments, where high precipitation provides appropriate stream and forest environments for speciation and ecological diversification. Even small streams of the southern Blue Ridge exhibit essentially permanent flow regimes, thus providing reliable habitats for stream-dwelling salamanders having long larval periods. At the same time, high moisture conditions prevail throughout the forest, providing favorable habitats on the forest floor for even the tiniest terrestrial salamanders.

The broad distribution of streamside desmognathines in eastern North America, including the Appalachians, suggests that this mode of life represents the ancestral adaptive zone of the subfamily, and that the subfamily had its origins as a streamside taxon throughout the upland sections of the eastern half of the continent.

The aquatic modes of life shown by *L. marmoratus* and *D. quadramaculatus* may represent derived life histories. I view these species as specialists; their lengthy larval phases, large metamorphic sizes, and large adult sizes are seen as derived rather than ancestral character states, evolved in the unique, restricted ecological theater of the southern Appalachians. Likewise, *D. aeneus* and *D. wrighti* have derived life histories, evolved in the same environment as that of the aquatic species, but showing exactly the opposite trends, leading to direct development and miniaturization. Hairston (1986, 1987) demonstrated experimentally that predation and, to a lesser degree, competition can account for the observed spacing of species on the aquatic-terrestrial habitat gradient in the southern Appalachians. In extending the argument to an evolutionary time scale, Hairston accepted Dunn's (1926) and Wake's (1966) views that adaptive radiation in desmognathines has proceeded unidirectionally from the large aquatic species to the small terrestrial forms; he identified predation as the main selective factor driving the process. Whether the predation theory can account for the evolutionary diversification of streamside ancestors in both the aquatic and terrestrial directions, simultaneously, remains an open question.

New Publication Due Fall 1991

Contributions in Herpetology

published by the

Greater Cincinnati Herpetological Society

The Greater Cincinnati Herpetological Society will be publishing a book entitled ***Contributions in Herpetology*** in the Fall. This publication is a compilation of an estimated 16 herpetological papers, covering a diversity of topics, and written by over two dozen authors. Moreover, the Society is dedicating this publication to Roger Conant and Hobart M. Smith in recognition of their life-long contributions to the field of Herpetology.

Specifications: softbound, approximately 125 pp., color cover photos, black and white in-text photos, tables, and an index of scientific names.

Authors and subjects include: Jose L. Camarillo-R. and Hobart M. Smith (the amphibians and reptiles of the state of México); David Chiszar, Scott A. Weinstein, and Hobart M. Smith (venom yield of *Boiga irregularis*); Roger Conant (presumed population status of various *Agkistrodon* species); James L. Glenn, Robert Nohavec, and Louis Porras (venom toxicity of *Hydrodynastes gigas*); William K. Hayes, David Duvall, and Gordon W. Schuett (courtship behavior in free-ranging *Crotalus viridis viridis* in Wyoming); Sherman A. Minton (reptiles as sources of human infections); and Karl H. Peterson (captive breeding of *Bothriechis lateralis*).

A special ***pre-publication*** price of U.S. $17.00 each (postpaid) is being offered for domestic orders received (with payment) ***on or before*** 1 October 1991. For orders placed ***after*** 1 October 1991, the price will be U.S. $22.00 each (postpaid). Bookseller inquiries are invited — if interested contact the Society for prices.

For foreign orders (outside U.S.) the price will be U.S. $19.00 each for orders placed **on or before** 1 October 1991 and U.S. $24.00 each for orders placed **after** 1 October 1991 (books will be sent postpaid-surface mail). Do not send payment with order. A Proforma invoice will be sent to you due to variences in currency conversion charges.

Payment in U.S. funds only. Make payable to: Greater Cincinnati Herpetological Society (or GCHS). ***Send orders to:*** Greater Cincinnati Herpetological Society, c/o Cincinnati Museum of Natural History, 1720 Gilbert Ave., Cincinnati, OH 45202 U.S.A. Attn: Contributions in Herpetology.

ANESTHESIA AND TRANSMITTER IMPLANTATION EFFECTS ON GRAVID GARTER SNAKES (*THAMNOPHIS SIRTALIS* AND *T. ELEGANS*)

Radiotelemetry is being used with increasing frequency in the study of snake ecology (e.g. King and Duvall 1990; Charland and Gregory, In Press). Its utility rests, in part, on the assumption that neither the transmitter nor the implantation technique affect the behavior of the animal. The simplest method of placing a transmitter into a snake is through force-feeding. However, there is evidence that force-feeding transmitters to snakes causes a "feeding effect," in which the animal shows reduced movement similar to that found following the ingestion of food items (Fitch 1987). In addition, some snakes show a thermophilic response following feeding (Lillywhite 1987, Lutterschmidt and Reinert 1990) and transmitter ingestion may confound studies of thermoregulation.

Recently, surgical implantation of transmitters has become common and a number of anesthetics have been used in these procedures (e.g., ketamine, Weatherhead and Anderka 1984; methoxyflurane, Aird 1986; halothane, Larsen 1987). However, there is little information on the long term effects of these implantation techniques.

Gravid females of viviparous species would seem to be particularly vulnerable to side effects not only from the anesthetic, but also because the mass of the transmitter may interfere with the developing embryos. As part of a larger study on thermoregulation by gravid garter snakes (*Thamnophis*), I collected data on the effects of anesthesia and surgical implantation on gestation.

Gravid female *T. sirtalis* and *T. elegans* were collected by hand on the Creston Valley Wildlife Management Area, Creston, B.C. (49° 6' N, 116° 31' W, elevation 1700 m). The animals were housed in plastic shoeboxes with water provided *ad libitum*. The shoeboxes sat on a concrete floor and were never exposed to direct sunlight. Heat was provided by a heating pad placed so that one-quarter of the floor area of each box was heated.

A complete experimental design that would allow me to examine each aspect of the implantation prodecure and any interactions would require a considerable number of gravid females. For my purposes, I was interested only in whether the implantation procedure, as a whole, disrupted gestation and I chose a simpler design using fewer snakes. My original 2 conditions were 1) anesthesia and transmitter implantation, and 2) control (no anesthesia or implantation). In addition, I attempted to look at the effect of anesthesia alone by adding a third group consisting of animals that had been anesthetized only. I, therefore, had 2 studies with a common control. Since these studies do not represent a complete experimental design, the results must be interpreted cautiously.

The animals were assigned randomly (within species) to one of the three treatments: anesthesia only, anesthesia and

Table 1. Capture and parturition dates of *Thamnophis sirtalis* and *Thamnophis elegans* under different treatment conditions. (A) anesthesia only, (I) anesthesia and transmitter implantation, (C) control. Anesthesia and implantation procedures took place on 18 and 19 June 1988.

Species	Treatment	SVL (mm)	Capture Date	Parturition Date	Litter Size
T. s.	A	540	17 May	12 July	10
T. e.	A	475	12 May	11 July	9

T. e.	C	535	17 May	6 July	9
T. e.	C	590	4 June	22 July	9

transmitter implantation, or control. The anesthetic used was methoxyflurane (Pitman-Moore, Inc., Washington Crossing, NJ) following the procedure of Aird (1986). A small volume of methoxyflurane was placed on a gauze pad by inverting the bottle once. The pad was placed in a capped 750 ml jar with the snake. Anesthesia was generally complete within 5 min, as shown by the flaccid appearance of the snake and the lack of a righting reflex. Recovery usually took from 1-2 h, at which time the snakes appeared to be behaving normally.

The transmitters used for implantation were models of those that I used for monitoring free-ranging gravid females (Custom Telemetry and Consulting, Inc., Athens, GA). The models were constructed of modelling clay and measured 8mm x 22 mm with a 12.7 cm whip antenna of flexible, plastic coated wire. The assembly was sealed in Plasti-Dip (PDI, Inc., Blaine, MN) and had a mass of ca. 4 g upon completion.

Following anesthesia a vertical incision was made in the snake's side anterior to the mass of developing embryos and the body of the transmitter inserted posteriorly. The transmitter was then massaged under the rib cage to lie extraperitoneally. The antenna was seated by running a 2 mm diameter plastic tube under the skin anterior to the incision and then sliding the antenna into it. The plastic tubing was then withdrawn through a small incision made at its anterior end leaving the antenna lying straight along the side. All incisions were then closed using 3-0 chromic sutures. The entire procedure typically took 20 min, including anesthesia.

Anesthesia and implantatiion of transmitters took place on 18 and 19 June 1988. This corresponded with the implantation of functioning transmitters into free-ranging study animals that were at a similar stage of gestation. Table 1 shows the parturition dates and litter sizes for *T. sirtalis* and *T. elegans* in the different treatments. There were no apparent differences in the parturition dates related to treatment and there were no stillbirths or obvious developmental anomalies among the neonates.

Parturition dates of captive animals were earlier than for snakes in the wild by 2-4 weeks, possibly because of the constant availability of a heat source in captivity. During the summer of 1988 parturition in the wild took place in the second and third weeks of August. One observation suggests that snakes in the wild were unaffected by the transmitter implantation technique. On 7 August I recaptured a gravid *T. elegans* that I was monitoring in the field (original capture, anesthesia, and implantation 9 July, release 12 July) because her transmitter had slipped out from under her ribs and appeared to be causing an abrasion. I returned her to the laboratory, anesthetized her and adjusted the transmitter position. On 12 August, just before release, she gave birth to a litter of eight neonates. There were no stillbirths or obvious developmental abnormalities.

These limited data suggest that this transmitter implantation technique may not interfere with the gestation of *T. sirtalis* and *T. elegans*. However, these data do not address the possibility that implantation influences aspects of the animal's physiology or behavior other than gestation, or that there may be long-term effects that do not manifest themselves until after the transmitter has been removed and the snake released. Given the popularity of radiotelemetry as a technique in snake ecology, this is an area in which much more work needs to be done.

SOFT PLASTRA OF ADULT MALE SEA TURTLES: AN APPARENT SECONDARY SEXUAL CHARACTERISTIC

In contrast to many turtle species, chelonid sea turtles do not exhibit sexual size dimorphism (Carr 1952; Pritchard 1979). However, chelonid sea turtles do have several sexual dimorphisms (Carr 1952; Pritchard 1979) that appear to facilitate successful mating. Adult males have long prehensile tails with a heavy terminal nail in contrast to adult females whose tails barely reach the rear margin of the carapace. The claws on the front flippers of adult males are longer and more strongly curved than those of adult females. Additionally, the posterior portion of the carapace of adult females is commonly more rounded than that of adult males. Collectively, these morphological characteristics enhance a male's ability to successfully mount a female. These secondary sexual characteristics also provide a means by which investigators can sex adult chelonid turtles and thus, are of importance to population studies.

We have observed what we suspect is an additional secondary sexual characteristic in chelonid sea turtles. Figure 1a shows the plastron of an adult male loggerhead, *Caretta caretta*, captured in the Cape Canaveral ship channel during April of 1983. The scutes on the medial portion of the plastron are relatively soft, lacking the hard cornified layer and exposing relatively soft and leathery epidermal tissue. These soft areas do not appear to be skin separating the scutes, such as that seen in musk turtles, *Sternotherus* spp. Rather, these areas appear to be scutes which lack a cornified surface.

We initially observed soft plastra on adult-sized male loggerheads (straight carapace lengths of 80 cm or greater) that were captured by trawling (as described by Henwood 1987) in the Cape Canaveral ship channel from 13 April 83 through 19 April 83. The soft areas of the plastra

varied in size, the smallest comprising the medial area of the anal scutes (Fig. 1b), whereas the largest included the medial portion of the entire plastron (Fig. 1a). While a complete survey was not taken of the 73 adult-sized males captured during the trawling, soft plastra appeared to be prevalent, but a well cornified plastron was noted for one adult-sized male (straight carapace length of 97.3 cm). All immature loggerheads (n=17) and adult-sized female loggerheads (n=5) captured during the trawling had well-cornified plastra.

We initially suspected that these soft areas may have resulted from abrasions during recent matings. However, several of the turtles had barnacles growing on these areas (Fig. 1b) suggesting that they had not been abraded by recent mating. It is possible, however, that barnacles may have grown on the plastra since the last mating.

Soft plastra have also been observed on adult male loggerheads from the waters of Heron Island Reef on the southern portion of the Great Barrier Reef (Colin Limpus, Queensland National Parks and Wildlife Service, pers. comm.). We have also observed soft plastra on adult male black turtles, *Chelonia agassizi*, that were captured off the coast of Michoacan, Mexico, near Playa Colola during November of 1989 (n=11). Adult female black turtles (n=8) captured in the same area had well-cornified plastra. Additionally, 15 adult male Kemp's ridleys, *Lepidochelys kempi*, maintained in captivity in Texas and on the Cayman Islands had soft plastra (Fig. 1c). Five of these males were maintained in separate tank and thus had no opportunity to mate. The 15 adult female Kemp's ridleys at those same facilities all had well-cornified plastra (Fig. 1d). The plastra of the adult male Kemp's ridleys at Cayman Turtle Farm, Ltd., remained soft over a 14 month period. To date, there have been no published reports describing plastra of male Kemp's ridleys from the wild. However, soft plastra are apparent in a published photo of a male olive ridley, *Lepidochelys olivacea*, captured off the coast of California (Hubbs 1977) and in the photo of a male olive ridley (Fig. 1e) captured off Oaxaca, Mexico (photo courtesy of John Hendrickson, University of Arizona).

We speculate that soft plastra could enhance a male's mating ability by increasing tactile sensation and/or by decreasing slippage during mounting. The lack of a soft plastron on one adult-sized male loggerhead captured in the Cape Canaveral ship channel suggests that soft plastra may not be exhibited by all adult males, that they may be temporary phenomena, or that some of the adult-sized loggerheads we observed may have been sexually immature. It is conceivable that soft plastra occur only on males that are reproductively active. Multiannual reproductive cycles are well documented for female sea turtles (Carr 1952), but only a few studies have addressed reproductive cycles in male sea turtles (Limpus 1985; Wibbels et al. 1987; Wibbels et al. in press). Those studies suggest that while many adult loggerhead appear to be reproductively active on an annual basis (Limpus 1985; Wibbels et al. 1990), some may not be reproductively active during a given breeding season (Wibbels et al. 1987). Future observations are required to determine if soft plastra 1) are of significance to sea turtle reproduction, 2) occur in other sea turtle species, and 3) occur on a temporary or permanent basis.

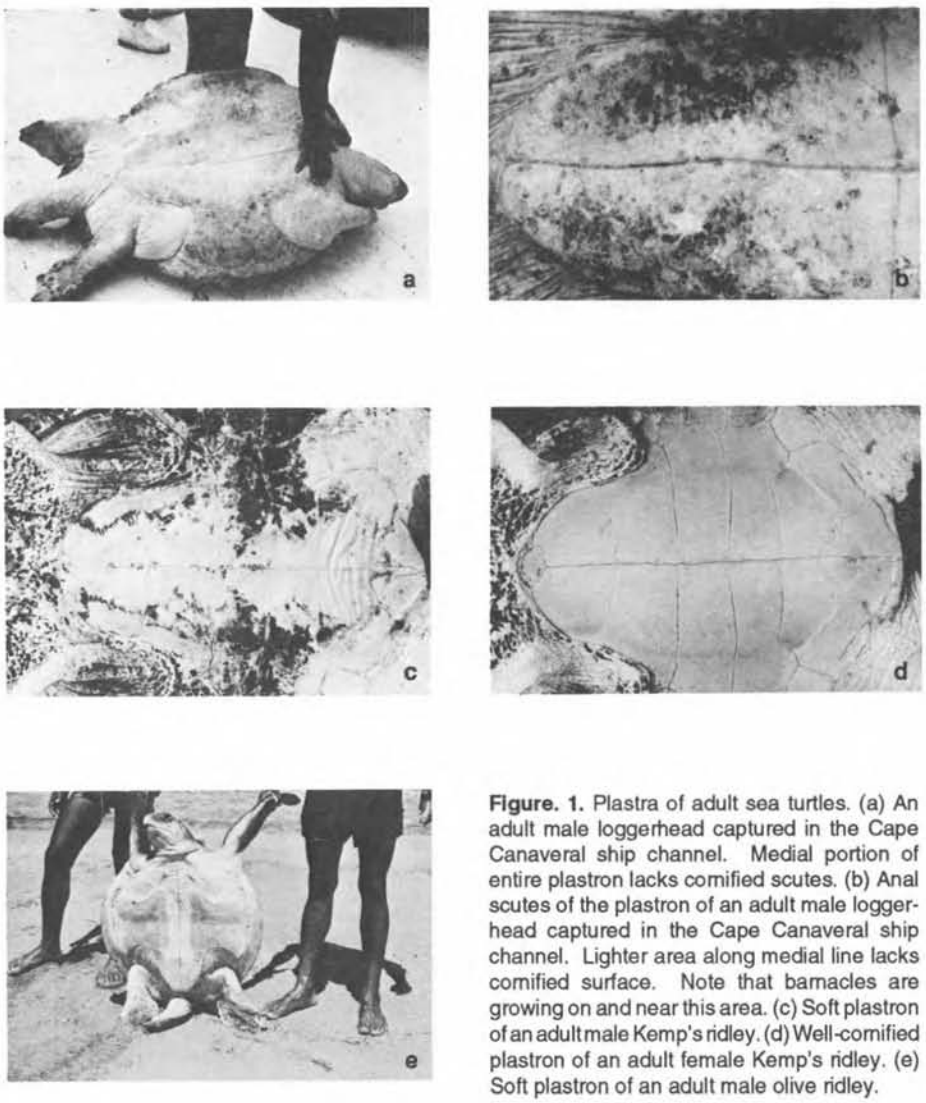

Figure. 1. Plastra of adult sea turtles. (a) An adult male loggerhead captured in the Cape Canaveral ship channel. Medial portion of entire plastron lacks cornified scutes. (b) Anal scutes of the plastron of an adult male loggerhead captured in the Cape Canaveral ship channel. Lighter area along medial line lacks cornified surface. Note that barnacles are growing on and near this area. (c) Soft plastron of an adult male Kemp's ridley. (d) Well-cornified plastron of an adult female Kemp's ridley. (e) Soft plastron of an adult male olive ridley.

ACKNOWLEDGMENTS

The observations reported here were recorded while conducting several collaborative studies on the reproductive physiology and behavior of sea turtles. We would like to extend our appreciation to our collaborators: Terry Henwood, Fred Berry, Charles Caillouet, Clark T. Fontaine, and Dickie Revera of the National Marine Fisheries Service, Colin Limpus of the Queensland National Parks and Wildlife Service, John Kerivan and Edward Lewis Jr. of SeaArama Marine World, Ila

Loetscher and Evelyn Sizemore of Sea Turtles, Inc., Jim and Fern Wood of the Cayman Turtle Farm, Ltd, Javier Alvarado of Universidad de Michoacan, and Janice Grumbles of Texas A&M University. Funding for these studies was provided by National Marine Fisheries Service Contract No. NA81-GA-C-00039, Sea Grant No. NA85AA-D-SG-128, and NSF No. BNS 84-18538.

AN INTERSPECIFIC SATELLITE PAIR ASSOCIATION BETWEEN *HYLA CHYRSOSCELIS* AND *HYLA VERSICOLOR*

Although morphologically similar, the two species of the gray treefrog complex can be separated on the basis of chromosome number (*Hyla chrysoscelis*: 2n = 24; *H. versicolor*: 4n = 48; Wasserman 1970). The two species also differ in the pulse rate of the mating call with the pulse rate of *H. versicolor* being slower than *H. chrysoscelis* when both species call in the same chorus (Zweifel 1970; Jaslow and Vogt 1977). Although both species may occur sympatrically (Johnson 1966; Ralin 1968; Zweifel 1970; Jaslow and Vogt 1977; Bogart and Jaslow 1979; Hillis et al. 1987; Johnson 1987; Little et al. 1989), there are no reports of behavioral interactions between the two species in the field. We now report the occurrence of *H. versicolor* from western Tennessee and apparent differences in habitat preferences between *H. versicolor* and *H. chrysoscelis*. We also report an apparent satellite association between an adult male of *H. chrysoscelis* and an adult male of *H. versicolor*.

The study site is located ca. 20 km north of Memphis, Tennessee on the Memphis State University Meeman Biological Field Station (= field station) ca. 5.4 km east and 60 m above the banks of the Mississippi River. A population of *H. chrysoscelis* became established at the study site in 1987 when cattle tanks filled with water were placed next to a wooded area. Observations were made during the 1988-90 breeding seasons when frogs were captured, weighed, marked, and released at the point of capture.

Amplectant pairs were collected in 1988 at oviposition sites (cattle tanks), placed in plastic containers filled with 6-8 cm of pond water, and allowed to complete oviposition. Eggs were incubated and hatched at room temperature, after which samples of tadpoles from each clutch were placed in 0.005% colchicine solution for 24 hr and chromosomes were prepared from tadpole tail epithelia according to the procedure of Bogart (1967). During 1989, chromosome counts were determined for adult male gray treefrogs sampled at another chorus site, a roadside ditch ca. 1.73 km NW of the field station. Heparinized whole blood (obtained by cardiocentesis) was transferred to culture vials containing 5 ml of McCoy's 5A medium supplemented with 20% fetal calf serum, 0.1 ml of pokeweed mitogen, and 0.1 ml solution of penicillin-streptomycin-amphotericin B (antibiotic-antimycotic, GIBCO). Details of cell culture and harvest have been described previously by Beck and Mahan (1979). In addition to chromosome analyses, a representative sample of advertisement calls were recorded on a portable Panasonic tape recorder. Call differences between *H. chrysoscelis* and *H. versicolor* can be perceived by the human ear without

bioacoustical analysis if both species are heard together in the same chorus (Zweifel 1970; Bogart and Jaslow 1979).

Chromosomal analysis of tadpole tissues from twelve clutches obtained from the field station revealed that all were diploid confirming our initial identification based on call parameters of males except for one (#65) that we identified as *H. versicolor*. Male #65 was captured on three of 18 nights at the field station during 1988, the last being on 25 July during a chorus of 41 males. On this night (2300 h, 24° C, > 95% humidity), after 3.9 mm of rain, we detected a satellite male (#139) crouched silently below calling male #65 ca. 20 cm distant in a posture typical of satellite males observed in our population and elsewhere (Roble 1985). We sampled the chorus continuously from 2030 to 2300 h prior to observing male #139 and did not observe him call earlier in the evening. Thus, it was unlikely that he was resting between calling activity. Additionally, the next nearest calling male to male #139 (besides male #65), identified as *H. chrysoscelis,* was ca. 2 m distant so that male #139 was unlikely assuming satellite behavior in response to another nearby calling male. We also did not hear male #139 calling before we approached male #65 so our presence was not responsible for the quiet behavior of male #139. We first caught male #139 on 11 July and identified him as *H. chrysoscelis* based on call parameters. His SVL was 40.0 mm and mass was 5.0 g; SVL of male #65 was 56 mm and mass was 11.2 g. The body size of male #139 suggested that this individual recently reached sexual maturity because males in western Tennessee begin calling just before reaching 40 mm SVL (Ritke et al. 1990). Later during the evening of 25 July, male #65 was found in amplexus with female #131. We were unable to sample tadpoles from this clutch and thus could not determine species identity for this female; she was not captured again.

Based on call parameters and chromosome counts, our sample of gray treefrogs at the field station during 1988 (204 males, 152 females) was comprised of *H. chrysoscelis* with one male identified as *H. versicolor* (male #65). The size relation between *H. chrysoscelis* and *H. versicolor* (male #65 was 3.0 mm longer in SVL than the largest *H. chrysoscelis* captured during the 1988 breeding season at the field station; see Ritke et al. 1990) is similar to that reported for sympatric populations in the midwestern United States where males of *H. versicolor* average larger than males of *H. chrysoscelis* (Jaslow and Vogt 1977; Bogart and Jaslow 1979; Matson 1990). This relation, however, may not hold for other geographic areas (Ralin 1968).

Chromosome counts of calling males (N = 8) sampled from the roadside ditch revealed that four were diploid (= *H. chrysoscelis*) and four were tetraploid (= *H. versicolor*). This agreed with our initial identification of these frogs based on call parameters. Although we did not perform a chromosome count of male #65 from the field station during 1988, his call pattern was similar to males of *H. versicolor* sampled from the roadside ditch during 1989 that were identified by chromosome counts.

The finding that satellite associations within the gray treefrog complex may be comprised of both species has not been previously reported. Such a scenario might lead to hybridization between *H. chrysoscelis* and *H. versicolor* if satellite males intercept gravid females as they approach calling males in order to initiate amplexus, as has been suggested for *H. chrysoscelis* (Roble 1985).

A tentative distribution map for *H. chrysoscelis* and *H. versicolor* (Romano et al. 1987) indicated that *H. versicolor* did not occur in western Tennessee. Our chromosomal analyses, however, confirmed that both species are common below the bluffs of the Mississippi River and form mixed-species choruses. The chorus site along the roadside ditch is ca. 3.0 km east of the Mississippi River and along with the surrounding forested areas, frequently floods during the spring rains (March-May). Based on auditory sampling of adult males along the roadside ditch during 1990, *H. versicolor* comprised 20-60% of chorusing males. However, population estimates of *H. versicolor* from the field station and from three other chorus sites (described in Ritke et al. 1991) that are also located on the bluffs above the Mississippi River comprised < 3.0% of the chorusing males. Apparently, *H. versicolor* prefers the bottomland conditions more characteristic of the Mississippi River floodplain where moisture levels (standing water and humidity) are greater than on the surrounding bluffs. These observations agree with those of Ralin (1968) who found that *H. versicolor* preferred more humid conditions than *H. chrysoscelis*, even in the same habitat. Although such preferences may influence the local distribution of both species of gray treefrogs, it is unclear what effects such preferences may have on the overall geographic distribution of *H. chrysoscelis* and *H. versicolor*.

ACKNOWLEDGMENTS

Special thanks to Alan P. Jaslow for confirming the identity of male #65 based on call parameters and for greatly improving an earlier version of the manuscript. Jeffrey G. Babb and Mary K. Ritke provided expert field assistance during the course of this study.

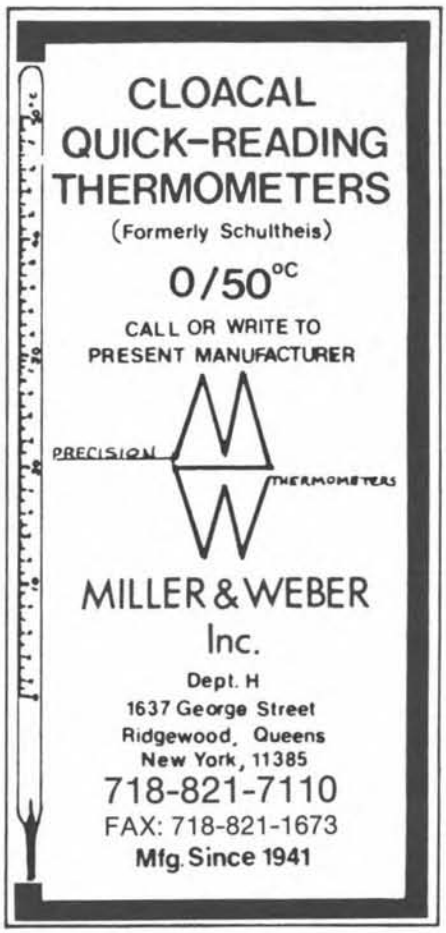
TECHNIQUES

A SAFE AND SIMPLE METHOD OF BLOOD COLLECTION FROM RATTLESNAKES



The collection of blood samples from living animals is a routine requirement of many research protocols. Cardiac puncture is the most commonly used method for blood collection from living reptiles (Sooter 1955; Dessauer 1970; Branch 1973; Cooper and Jackson 1981). However, this method carries the risk of mortality from cardiac tamponade as a result of blood effusing into the pericardium (Coulson and Hernandez 1964; Wallach 1971). It can also be difficult to master and, because of the need to work in the anterior region of the body, dangerous for the researcher sampling unanesthetized venomous snakes.

Blood can also be collected from the caudal artery or caudal vein of lizards and snakes by inserting a needle through the mid-ventral region of the tail (Esra 1975). Collecting blood from caudal vessels is less dangerous for the animal and the investigator, but it too can be difficult to master because of variation in the location of vessels (Brazaitis and Watanabe 1982). Here we describe a safer, simpler and comparatively less traumatic method for collection of blood from the caudal vessels of rattlesnakes.

We restrain the snake in a squeeze box having one open end (modified from Quinn and Jones 1974) so that its tail remains outside the box. Any restraining method that leaves the rattle accessible would be suitable (e.g., Gillingham et al. 1983; King and Duvall 1984). Blood collection is made using a sterile, disposable 1 cc tuberculin syringe fitted with a sterile disposable needle. We use a 21 G 1" needle for snakes over 60 cm total length and a 26 G 3/8" for smaller specimens. Larger bore needles are used whenever possible to improve flow rate and reduce damage to the rather large blood cells. The distal portion of the tail and proximal portion of the rattle is swabbed with 70% isopropyl alcohol. The needle is inserted at an obliquely posterior angle between the first and second proximal segments on the ventral side of the rattle (Fig. 1). This places the tip of the needle into the living tissue contained within the terminus of the proximal (basal) rattle segment. Gentle suction is created by very slowly pulling the syringe plunger. To achieve maximum blood flow, it is occasionally necessary to reposition the tip of the needle in the tissue by rotating it, or slightly increasing or decreasing the penetration until a caudal vessel is punctured. The greatest flow rates and yields are obtained when the body temperature of the snake is relatively high (25° to 30° C), and the tail is positioned lower than the rest of the snake's body. Warming the tail in the palm of the hand or briefly submerging it in warm water may also increase blood flow.

After collection, the blood is immediately transferred to sterile blood tubes containing heparin or EDTA. To reduce damage to blood cells, the needle is removed from the syringe before expelling the blood, and mixing is accomplished by gentle rotation (Kaplan 1968). In most cases clotting of the needle puncture occurs very rapidly, but the clotting speed can be enhanced by briefly applying direct pressure to the puncture site with an alcohol swab.

We have used this technique to collect 64 blood samples from 52 timber rattlesnakes (*Crotalus horridus*) ranging in size from 43.6 cm to 126.8 cm in total length (70 g to 1680 g in body mass).

Several snakes have been subjected to repeated sampling over the past two years. No visible injury or infection has been noted, and subsequently formed rattle segments appear to have developed normally. Using this method, we have drawn single sample volumes as large as 1.0 ml from adult *C. horridus*. However, we normally collect between 0.25 and 0.50 ml of blood in a single sampling. This technique should be suitable for most rattlesnakes that have a total length of greater than 45 cm.

HERPETOLOGICAL HUSBANDRY

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented materiel to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, are frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Lyndon A. Mitchell, Department of Reptiles and Amphibians, Dallas Zoo, 621 East Clarendon Drive, Dallas, TX 75203, USA.

CAPTIVE BREEDING OF THE TIMOR MONITOR (*VARANUS TIMORENSIS SIMILIS*)

Varanus timorensis is a small monitor that ranges through northern Australia, New Guinea, and Timor; the subspecies *V. t. similis* occurs in northeastern Australia and southern New Guinea (de Bitter 1981, Cogger 1983). Relatively little information has been published concerning the reproductive biology of this species. This report describes reproduction in a captive group of three male and one female *V. t. similis*. Courtship and copulation occurred in three consecutive years, and young were successfully hatched and raised from two of the three clutches of eggs that the female produced.

Materials and methods

Three wild-caught adult male and one female *V. t. similis* were obtained from animal dealers in 1980-81. The males measured approximately 210, 210, and 220 mm in snout-vent length (total lengths 510, 490, and 470 mm), and the female, 210 mm (TL 515 mm). The lizards were maintained in a glass-fronted wooden terrarium measuring 195 X 36 X 60 cm high. Branches and rocks were provided, and the cage floor was covered with newspaper, under which the lizards frequently hid. Water was available in a large, shallow pan, and a box of dry soil was present, into which the lizards occasionally burrowed, and in which eggs were deposited. A single 60W incandescent bulb provided a hot-spot for basking, and the terrarium was also illuminated by a 40W Vita-lite fluorescent tube. A variety of foods was provided, including crickets, small mice, whole fish, earthworms, and canned dogfood. The lizards were fed two to three times per week. Light cycle was ca.12L:12D, but this schedule was not rigorously maintained. Daily temperatures were 26-30°C, with night temperatures of 20-23°C. Conditions remained the same throughout the year.

Eggs were removed within several hours of laying in each case and incubated on a raised aluminum screen in a glass-covered 40 L aquarium with approximately 1 cm of water on the bottom. This tank was placed inside a thermostatically controlled wooden incubator, and the eggs were maintained at 90-100% humidity at a temperature of 28-30° C.

Young were housed individually in 60 L aquaria with newspaper substrate and cardboard tubes for shelter. Terrarium lighting and temperatures were similar to those for adults. The young were fed 3-4 times per week on crickets, baby mice, earthworms, catfood, and small fish, with vitamin and mineral supplementation once weekly.

Observations and discussion

Although three male monitors were present in the group, only one male was observed copulating with the single female. This male, the largest and most heavily built individual, was clearly the dominant animal in the group. Not only did it appear to be the only male to successfully copulate, but it was also the most aggressive feeder, often driving the other lizards away from food. Moehn (1984) suggested that short-term pair-bonding may occur in *V. timorensis*; since in this

case the same male mated with the same female for three consecutive years, longer-term bonding might also occur, at least in captivity. Alternatively, this male's mating success could simply be due to its dominance in the social group. Auffenberg (1981) also reported pair-bonding in a varanid (*V. komodoensis*).

Courtship and copulation were only observed during a short period in each year in which reproduction occurred (Table 1). During each breeding period, the male was observed pursuing the female and repeatedly copulating with her throughout the day. Detailed data on mating behavior were not collected; however, Moehn (1984) published observations of courtship and copulation in this species. Observations of this group of *V. timorensis* support Moehn's (1984) conclusion that the breeding season is short in this species, and the fact that it occurred at the same time each year for three consecutive years suggests that reproductive activity may be determined by an "internal clock", since conditions for this captive group did not vary throughout the year. The breeding period for this group coincided closely with that reported by Moehn (1984), who observed courtship and copulation between 9 and 20 February in a captive pair of *V. timorensis*.

Prior to egglaying, the female monitor's stomach appeared swollen, but gravidity seemed to have little effect on her behavior; each year, she remained active and fed normally up to the day of egglaying. Eggs were laid in dry soil, loosely covered, in each year. The female became very active and fed voraciously for several weeks after oviposition in each case.

In each year, eggs that failed to develop showed heavy fungal growth and collapsed within a week of laying. Young hatched in 1983 began feeding on small crickets five to six days after hatching; 1984 young took crickets within a week of hatching.

The times for egglaying for *V. t. similis* given here (Table 1) differ from those reported by de Bitter (1981) and Behrmann (1981) for *V. t. timorensis* (18 May, and 4 and 6 September, resp.). Possibly, breeding habits are different for this subspecies. The incubation periods reported here (Table 1) are within the range previously published for *V. timorensis*. Incubation periods described by de Bitter (1981) were 135 and 140 days; Behrmann's (1981) eggs hatched after 93 and 100 days; and Rüegg (1974) reported an incubation period of 139-140 days for *V. t. similis*.

All four young were healthy and feeding well as of October 1986, but their growth to that time was slow. Of the two hatched in 1983, the larger measured ca. 135 mm snout-vent (total length 340 mm, mass 47.9 g), and the smaller, 135 mm s-v (TL 330 mm, mass 31.8 g). The larger of the two hatched in 1984 was 145 mm s-v (TL 365 mm, mass 32.4 g), and the smaller, 140 mm s-v (TL 355 mm, mass 34.5 g).

Table 1. Mating, egglaying, incubation and hatchling data for *Varanus timorensis similis*.

	1982	1983	1984
Time of Mating Activity	first week Jan.-first week Feb.	first week Jan.-first week Feb.	mid-Jan.-mid-Feb.
Egglaying date	28 Feb.-1 March (overnight)	27-28 Feb (overnight)	15 March (afternoon)

LIFE HISTORY NOTES

Life History Notes is analogous to Geographic Distribution. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword which best describes the nature of their note (e.g., Reproduction, Longevity, Morphology, etc.). Figures are permissible to illustrate any data, but should **replace** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance.

Standard format for this section is as follows: SCIENTIFIC NAME (in caps), COMMON NAME (lower case, in parentheses) as it appears in Collins (1990. **Standard Common and Current Scientific Names for North American Amphibians and Reptiles, 3rd ed.**, Herp. Circ. 19:1-41), KEYWORD (in caps). DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (Name(s) in caps, and address(es) in full). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to a recent issue for citation format).

ANURA

BUFO BUFO (European Common Toad). **REPRODUCTIVE MORTALITY**. The

breeding season of *Bufo bufo* in southern England may be as short as two or three weeks and, on any one night over the course of the season, there may be as many as five males for every female. Males obtain mates by searching for unpaired females and by attempting to displace males already engaged in amplexus with females (Davies and Halliday 1978. Nature 274:683; 1979. Anim. Behav. 27:1253). We observed mating behavior in a population of *Bufo bufo* breeding in a small culvert connected to Willen Lake in Milton Keynes, Buckinghamshire, England, on 9 and 10 March 1985. Mating activity at this site was especially conspicuous due to the presence of large "mating balls" of writhing toads on the substrate of the culvert. We removed eight balls from the water, and determined the sex composition of each. Each ball consisted of a single female toad surrounded by from five to fourteen males (mean number of males = 9). Three of the eight females were dead. In one case, a string of spawn extended from the cloaca of the dead female. Similar sex-differential mortality has been reported in the frog *Rana sylvatica* (Phillips and Wade 1990. Herp. Rev. 21:59).

On 10 March we attempted to count the total number of adult toads present in the culvert. Only three females were found (all alive), all at the center of mating balls. Thirty males were counted in mating balls, and at least 30 single males were observed. We thus estimate the operational sex ratio to be highly skewed towards an excess of males. We counted no more than 10 strings of spawn in the culvert over the duration of the breeding season, further evidence for a preponderance of males at this site.

Whether mating balls are the cause of female mortality or whether they simply form around dead females is unclear. However, if the former is the case, mortality due to intense competition among males may represent a significant cost of reproduction for female *Bufo bufo*. It may also have a severe negative effect regarding population survival, especially for populations of relatively small size.

BUFO PUNCTATUS* X *BUFO RETIFORMIS (Red-spotted Toad, Sonoran Green Toad). **NATURAL HYBRIDIZATION**. Hybridization in nature is widespread among bufonids (Sullivan 1986. J. Herpetol. 20(1):11-21). However, few natural hybrids have been observed in the *B. punctatus* group (Ferguson and Lowe 1969. Amer. Midl. Nat. 81(2):435-466). Herein we report the discovery of a natural hybrid between *B. punctatus* and *B. retiformis*.

On 21 July 1986, while road-riding on Route 15, 6.9 mi. NE of Quijotoa, Pima Co., Arizona, the first author discovered a hybrid female (Fig. 1) along the edge of a rain-formed pool. Using the following measurements of SVL (68.3 mm), tibia length (25.1 mm), parotoid length (9.5 mm), parotoid width (6.8 mm), eyelid length (7.8 mm), postorbital crest (POC) length (7.1 mm), and POC to POC distance (20.5 mm), we calculated five ratios and compared these to Ferguson and Lowe's (op. cit.) ratios for pure *B. punctatus* and *B. retiformis*, two likely candidates for the parent species. The presumed hybrid was intermediate to *B. punctatus* and *B. retiformis* in three of the five ratios (tibia length/parotoid length, 2.64; parotoid length/eyelid length, 1.22; and parotoid length/parotoid width, 1.40). SVL/parotoid width (10.98) was closer to *B. punctatus* while SVL/POC to POC (3.33) was closer to *B. retiformis*. Two other potential parent species, *B. alvarius* and *B. cognatus*, were eliminated because the presumed hybrid was: 1) dissimilar in body color; 2) lacked both warts on the legs and white warts at the angle of the jaw; and, 3) differed in cranial crest structure.

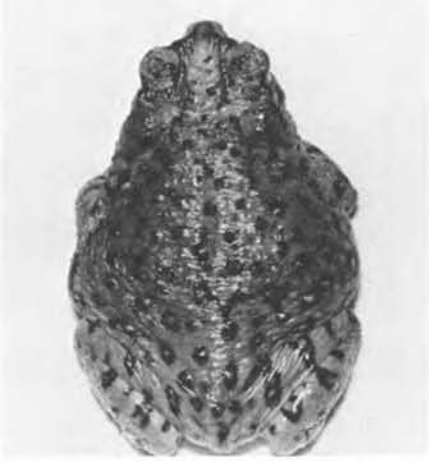

Figure 1. A natural hybrid between *B. punctatus* and *B. retiformis*.

Ferguson and Lowe (op. cit). crossed *B. punctatus* and *B. retiformis* in the laboratory and obtained metamorphosed offspring. However, until the discovery of this specimen, no natural hybrids were known. Although these parent species differ ecologically and behaviorally in zones of sympatry, hybridization might occasionally occur in high-density heterospecific breeding aggregations in which males may adopt alternative reproductive tactics such as active-searching or satellite behavior.

Submitted by **R. W. BOWKER**, Glendale Community College, Glendale, AZ 85301, USA, and **B. K. SULLIVAN**, College of Arts and Sciences, Arizona State University, P.O. Box 37100, Phoenix, AZ 85069-7100, USA

RANA TEMPORARIA (Common Frog). **MASS MOVEMENT**. *Rana temporaria* has a great tolerance of cold and breeds earlier in the year than any other amphibian; breeding migrations can sometimes involve mass movement (Fuhn 1960. Amphibia. Ed. Acad. R.P.R., Bucharest. 288 pp; Smith 1969. The British Amphibians and Reptiles. Collins, London).

On 24 April 1986 at 1200 h, a mass movement of this species was observed at Cîmpusel (1300 m alt.), on the East Jiu Valley, Retezat Mountains, Hunedoara Department, Romania. The snow was ca. 1 m high and air temperature was 16° C. At an elevation of 100 m on the other (and unshaded) side of the river, the snow was completely melted and active adders (*Vipera berus*) were observed. The warm air produced a rapid snow melt, especially around trees, fences, and paths. In this area, frogs were observed emerging from hibernacula and jumping towards the nearby stream. The area from where the frogs appeared was ca. 200 m^2, situated 10-20 m from the stream. Emergence from hibernation coincided with an increase in air temperature by noon; nighttime temperatures were below 0° C. The only observed breeding site was ca. 250 m downstream; ca. 20 animals were observed, mostly males. An amplexing pair was found close to the stream, resting on ice. When observed, the female started to creep and jump towards the stream.

The movement of frogs was in one direction and appeared synchronous, lasting only 30-40 min. Their slow pace may have been caused by the ice substrate and their emaciated condition. After reaching the stream they were carried away by the stormy waters and lost from sight. Four km downstream, in a clearing free of snow, a number of egg masses and tadpoles of *Rana temporaria* were observed.

Voucher specimens were deposited in the collection of the Deva Museum, Deva, Romania.

CAUDATA

PLETHODON VEHICULUM (Western Red-backed Salamander). **REPRODUCTION**. Although Carl (1943. Brit. Columbia Prov. Mus. Handbook, No. 2:1-62) reported a clutch/nest site of *P. vehiculum* from British Columbia, and two clutches have been reported from a single site in Oregon by Hanlin et al. (1979. J. Herpetol. 13(2):214-216), no natural nest sites of this species have been documented for Washington state. On 13 May 1989 such a nest site with a recently deposited (no embryos present) clutch was discovered on a N-facing slope (ca. 45° grade) inclining toward Dalco Passage (ca. 300 m distant) in an old-growth stand of mixed conifers and maples at Point Defiance Park, Tacoma, Pierce Co., Washington (T.21N., R.2E., Sec. 15). Two adult *P. vehiculum* (SVL = 52.5 mm female, 45.0 mm male) were in attendance. Both adults were close to the clutch, one within ca. 3 cm; however, sexes were not noted at collection.

Carl (1943) provided little detail and no quantitative data concerning the British Columbia nest site. However, the detailed report of Hanlin et al. (op. cit.) provides for interesting contrasts between the Oregon and Washington sites. Though no information provided by the Point Defiance nest site contradicts their determination of a Mode III reproductive strategy for *P. vehiculum*, no stream or seep occurs within the immediate proximity of the Washington site and no rocks were present as reported in association with the Oregon site.

The clutch was deposited directly on the substrate under a large (150 x 50 x 10 cm), oblong and irregular shaped bark slab of Douglas fir (*Pseudotsuga menziesii*), bark side up. Substrate was moist loamy soil, mixed with Douglas fir and hemlock (*Tsuga* sp.) needles and other organic debris. The opaque outer envelope exhibited reddish-brown adhering soil particles from the substrate; the living ova were yellowish-cream in color, the individual ova envelopes transparent.

Consisting of 11 ova, this clutch is the numerically largest naturally deposited clutch yet reported for *P. vehiculum*. Overall, the clutch measured 14 x 11 mm with the outer envelope intact. Various measurement ranges (in mm) of the ova, after 11 months of preservation in 10% isopropanol, are as follows (means in parentheses): greatest ovum length with individual gelatinous envelope, 5.1-6.1 (5.5); greatest ovum length not including individual envelope, 4.3-5.0 (4.7); greatest ovum width with individual envelope, 4.3-5.2 (4.7); greatest ovum width without individual envelope, 3.7-4.9 (4.2); greatest distance from ovum to outer edge of individual gelatinous envelope while suspended in fluid, 1.0-2.5 (1.7).

Observations of parental brooding behavior were attempted in the laboratory (19-20.5° C) at irregular intervals from (2100 h) 13 May 1989 until (1230 h) 18 May 1989 by which time the eggs (still in the outer envelope) had begun to exhibit indications of spoilage. Only the female was recorded to coil about the eggs. No brooding behavior per se was observed after approximately 1100 h 14 May 1989.

Sympatric invertebrates observed or collected at the site included slugs (*Ariolimax columbianus*), carabid beetles, terrestrial isopods (*Oniscus* sp.), and centipedes (*Scolopocryptops sexspinosus*). The presence of small invertebrates at the site may indicate a nest site choice providing a food supply for brooding adults, as discussed by Hanlin et al. (op. cit.).

Voucher specimens, including the adults, will be deposited in the James R. Slater Museum of Natural History (Accession #: BRN0142). We thank E. L. Karlstrom and D. R. Paulson for reviewing the manuscript.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). **PREDATION**. Ernst and Barbour (1989. Snakes of Eastern North America. George Mason University Press, Fairfax, Virginia. 282 pp.) summarized food habits of the pigmy rattlesnake, *Sistrurus miliarius*, and included frogs, toads, lizards, snakes, nestling birds, and mice as vertebrate prey. Although some prey is ambushed, Ernst and Barbour (op. cit.) suggested that most are actively sought. We report on the four-toed salamander, *H. scutatum*, as a new prey item of *S. m. streckeri* from Arkansas.

On 17 October 1990, one of us (BGC) came upon a snake/salamander interaction in an area marked "Wildlife Habitat Zone" in the Ouachita National Forest, Garland Co., Arkansas, just north of National Forest Road 384 (T.3S., R.22W., Sec. 32). The encounter was observed at 1115 h; the sky was clear, and the air temperature was ca. 24° C. The rattlesnake (a male, 408 mm SVL) was positioned in a very tight S-shape with its snout less than 25 mm from the right lower side of the salamander's trunk. The salamander (a female, 35 mm SVL) was slowly twitching its arms, legs, and tail, although the trunk and head remained still. Following these observations, both animals (Arkansas State University Museum of Zoology 16836 - snake; ASUMZ 16838 - salamander) were collected; the salamander died within five minutes after being placed in a plastic bag. The salamander was examined after fixation and revealed a 4 mm circular region of the lower right abdomen that was translucent compared to the surrounding tissue and suggests a possible site of envenomation.

TESTUDINES

CLEMMYS GUTTATA (Spotted Turtle). **SIZE MAXIMA**. An unusually large *Clemmys guttata* was captured April 1990 in a small pond in North Hampton, New Hampshire 0.3 miles E of U.S. Route 1 on Route 101D. The CL = 13.64 cm. Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston. 429 pp.) lists the record at 12.7 cm. No record of a larger specimen could be located.

The turtle was kept as a "pet" by a young man who presented it to a wildlife rehabilitator in September 1990 when the turtle demonstrated advanced symptoms of starvation. The turtle died within 24 h. The turtle was donated to the Museum of Comparative Zoology, Cambridge, Massachusetts (MCZR176001) where the CL was verified by José P. Rosado, Collection Manager.

GOPHERUS POLYPHEMUS (Gopher Tortoise). **DRINKING BEHAVIOR**. Various drinking behaviors have been described for tortoises inhabiting dry environments. Auffenberg (1963. Anim. Behav. 298(11):72-73) described how *Psammobates tentorious*, *Kinixys*

homeana, and *Homopus areolatus* use their unique shell shape and behavior of lifting the shell with the hind legs to direct water flow toward the front of the shell and the head. Desert tortoise (*Gopherus agassizii*) drinking was described by Luckenbach (1982. In R. B. Bury (ed.), North American Tortoises: Conservation and Ecology. USFWS Res. Rpt. No. 12:1-37). The only observation of drinking in this species is from puddles or springs; similar descriptions have been found in the literature for the *Gopherus polyphemus* or other species in the genus. We have observed gopher tortoises drinking from temporary ponds as they foraged after heavy rains. Temporary pools are uncommon in the sand hill habitat of this species except possibly during the rainy season.

Our initial observation of drinking behavior in *Gopherus polyphemus* was of a newly captured tortoise from recently destroyed sand dunes in St. John's Co., Florida. It was observed drinking at the mouth of its newly constructed burrow at the beginning of a heavy rain. Since that observation, we have observed this behavior on more than 30 occasions over the past four years. We have been able to entice tortoises into drinking at the mouth of the burrow when soil conditions were dry and it had not rained for at least ten days. Under normal circumstances, when the tortoise is approached while it is near the burrow's entrance, it retreats immediately. However, the tortoise appeared oblivious to human presence when drinking.

Figure 1. Gopher tortoise drinking at entrance to burrow.

When we have observed the tortoise drinking at the beginning of rain storms (n = 11) and when the burrow mouth was sprinkled moderately from a garden hose (n = 22), the behavior observed was the same. Upon arriving at the mouth of the burrow from below, the tortoise moves up to the point where it is just inside of the burrow mouth. It positions its body sideways so it is blocking the entrance to the burrow and its head is at the corner where the wall and floor of the burrow meet (Fig. 1). The foreleg facing the entrance is extended forward and into the surface of the sand. Any surface flow into the mouth of the burrow is interrupted by the extended leg and diverted toward the head. Upon arrival, the tortoise immediately forces its head into the sand to nearly eye level and begins to drink. The tortoise may drink in this manner for more than 4 min (n = 4), but most frequently for under 3 min (n = 12).

We measured the time it took the tortoise to appear from below the surface to the mouth of the burrow as we sprinkled the mouth. The mean response time was 1 min 28 sec; the shortest response time was 18 sec, the longest 3 min. If the ground was moist or if rain had been recorded, the tortoise would not respond. The depth of the burrow was measured at ca. 2.2 m.

During heavy rains, water seems to flow from several directions outside to either edge of the burrow which act as a gathering point or vortex. Particularly, water moves from the edge of the sand shelf in front, to the edges of the burrow's mouth.

Gopher tortoises generally inhabit well-drained, sand-based soils in upland habitats. Water percolates rapidly through these soils and rarely stands in puddles. Tortoises quite rarely have either permanent or ephemeral streams or ponds within their home ranges (Deimer 1988. Gopher tortoise status and harvest impact determination. Final report, Florida Game and Freshwater Commission. Tallahassee, Florida). Throughout most of this species' range, during its active period (ca. March-November), much of the precipitation falls in short-lived, heavy rains during convection thunderstorms. The drinking behavior documented here is a unique adaptation to a habitat where surface water may be available for very short, infrequent periods throughout most of the year.

TRIONYX FEROX (Florida Softshell). **REPRODUCTION**. A large female (PL 351 mm, CL 450 mm) collected 25 June 1976 on Payne's Prairie Preserve, Alachua Co., Florida and reported earlier by Iverson (1985. Florida Sci. 48:41-44), bore 5 sets of corpora lutea (11, 9, 5.5, 4, and 2 mm) and one set of 30 preovulatory follicles (17-19 mm). Luteal scars, by descending size class, numbered 28, 25, 16, 24, and 22; the largest set corresponded precisely to the number of oviducal follicles, only one of which was yet shelled. An additional unovulated follicle from each of the two sets was undergoing atresia. Observations of sporadic nesting in this population through July and into early August, as well as additional dissections revealing that preovulatory follicles are not retained through winter, strongly suggest that this female would have laid a sixth clutch in 1976. Her annual reproductive potential of 145 eggs for that year is by far the maximum confirmed for North American members of this genus (*Apalone*, sensu Meylan 1987. Bull. Amer. Mus. Nat. Hist. 186(1):1-101).

While my observations of incubation period (to hatching) at 27-30° C generally concur with those of Iverson (op. cit.), the following data from eggs of this population extend our knowledge of this species' development at cooler temperatures. Four eggs from two clutches pipped at 111-116 days, whereas all eggs incubated at 20° C died early during embryogenesis.

Research on Payne's Prairie was conducted via permits from the Florida Department of Natural Resources.

TRIONYX SPINIFERUS SPINIFERUS (Eastern Spiny Softshell). **BURYING BEHAVIOR**. According to Ernst and Barbour (1972. Turtles of the United States. Univ. Kentucky Press, Lexington. 347 pp.) the spiny softshell buries itself by flipping silt over its back until it is completely concealed. Carr (1952. Handbook of Turtles. Comstock Publ. Assoc., Ithaca, New York. 542 pp.) believed that the soft-margined shell is probably more of an adaptation for burying in the bottom than for aquatic locomotion. He noted "the ease with which it may be shuffled into the bottom soil by sidewise movements and the conspicuously low mound that it makes when so covered." Newman (1906. J. Comp. Neurol. Psychol. 16(2):126-152) reported two large female *T. spiniferus* confined in shallow water within a pen that buried themselves by rocking the body from side to side and throwing mud up to cover the carapace. This movement was continued

until they sunk deeper and had only the snout sticking out of the mud. Newman did not indicate how the animals "threw" the mud, but our observations of softshell burial indicate that the procedure employed is quite different. While all of our observations have concerned animals burying in sand substrates, M. Plummer (pers. comm.) has seen smooth softshells, *T. muticus*, bury in sand, mud, and gravel in the same manner we describe here.

During the course of field studies on *Trionyx s. spiniferus* near the mouth of the Lamoille River at Lake Champlain, Chittenden Co., Vermont, we watched hatchlings, juveniles, and adult males bury themselves in sandy underwater substrates. We made similar observations on young maintained in an aquarium with 3.5 cm of medium-grained sand obtained from the lakeshore where turtles were known to bury. In-tank water depth above the sand averaged 10 cm. Temperature was maintained at 24-25° C by a submersible aquarium heater.

Burying progresses as follows: the head is thrust into the sand and then partially retracted as powerful thrusts of the forelimbs and hindlimbs cause the turtles to literally "crawl" under the sand. The anterior end is drawn down into the sand as the forelimbs are first extended and then swept to the side to pull the animal forward. While the forelegs are pulling, the hindlegs are pushing (forwards and upwards) to assist forward momentum and at the same time raise the rear margin of the animal's carapace. After moving for several cm in this fashion the animal ceases forward movements and suddenly demonstrates a rapid waggle or shimmy of its rear end causing the sand to settle smoothly over the carapace. Normally, after the shimmy, the only indication of a buried softshell is a slightly elevated crescent-shaped ridge of sand left near its anterior end. This ridge forms just ahead of the turtle as it bulldozes its way through the sand.

The bury-and-shimmy behavior is demonstrated immediately post-hatching and is used thereafter by all subadults, adult males, and probably adult females. Although we have not observed burial in adult female *T. spiniferus*, M. Plummer (pers. comm.) has seen adult female *T. muticus* burying in the same manner, and has on occasion noted that females will bury out of water on a sandbar after first laying their eggs. In all cases when we have released adult female *spiniferus* in the wild, they have elected not to bury and have instead moved rapidly to deeper water. All other softshells we have released have adopted the bury-shimmy strategy. This behavioral adaptation enables them to lie inconspicuously buried in very shallow water.

It is common to find males and young spiny softshells buried right at the water's edge along sandy beaches and sandbars, but we have never found females in these situations. M. Plummer (pers. comm.) has seen female *T. muticus* bury right along shore in the nesting season, however. In Vermont, softshell burial during the warmer parts of the year is almost always in water that is shallow enough to allow the turtles to extend their long neck to the surface for air, without first emerging from hiding. Burial in shallow water also confers a thermal benefit (Plummer 1977. Copeia 1977(3):431-440). On two successive days Plummer found 110 *T. muticus* hidden along a sandbar where water temperature was 6.5° C higher than in the adjacent river channel. While hand-capturing buried *T. spiniferus* in Vermont on 28 June 1990, we took temperatures at four softshell burial sites and then along a 20 m transect extending lakewards through a bed of rushes to open water. Water temperature in the lake was 22° C but at the burial spots it was as high as 30.5° C.

We would like to thank R. Guthrie for graciously showing us how to track and locate buried softshells last spring in Alabama, and for calling their unique "shimmy," as he dubbed it, to our attention.

APALONE SPINIFERA (Spiny Softshell). **BEHAVIOR**. We observed a female spiny softshell (CL = 37.8 cm) squirt blood from both eyes in response to handling. The turtle was captured 27 June 1988 in Bayou Duplantier, ca. 0.5 km S of the Louisiana State University campus, Baton Rouge, Louisiana. The turtle was temporarily housed in a large plastic tub partially filled with water. On 2 July 1988 the tub was drained and the turtle removed. The turtle was in a state of obvious agitation as it was lifted from the tub and simultaneously emitted a jet of blood from each eye. This action was sudden and lasted ca. 1 sec. The blood was propelled ca. 15 cm at an angle of ca. 45° from the longitudinal axis of the head.

Repeated attempts at later dates to induce this behavior for further observation and photography proved unsuccessful. A similar blood spurting behavior has been noted in several species of *Phrynosoma* (Smith 1946. Handbook of Lizards. Comstock Publ. Assoc., Ithaca, New York. 542 pp.), but we are unaware of this behavior having been reported for any species of turtle.

SAURIA

ANOLIS CAROLINENSIS (Green Anole). **WINTER ACTIVITY**. On 31 December 1990 and 13 January 1991 an adolescent male was observed sunning itself in Athens, Georgia (33°56' N — 83°25' W); on the latter occasion the air temperature was no higher than 8° C. This lizard and two others had been seen repeatedly in chilly weather since October. They live in a pile of pinestraw on top of which is a black plastic sheet, resulting in temperatures higher than ambient. The climate of Athens is temperate, with first frost normally 15 October, but this winter was one of a series of mild ones and the temperature was below freezing only a few times.

Submitted by **MICHAEL A. COVINGTON** and **CATHY COVINGTON**, 285 Saint George Driver, Athens, GA 30606, USA

ANOLIS LIVIDUS (NCN). **FEEDING**. Anoles are typically reported as sit and wait predators with few exceptions. Prey descriptions based on stomach contents consist largely of invertebrates, presumably engulfed live. This note describes natural feeding by an anole on non-living matter.

On 19 June 1981 during a study of male *A. lividus* behavior on Montserrat, B.W.I., an anole was observed to descend to the ground, travel ca. 1 m, and begin feeding. The substrate here was well-shaded and generally consisted of bare, dark soil. Where the lizard was feeding, a conspicuous white spot was visible on the soil surface. The lizard repetitively grabbed at the white material and appeared to be consuming it. No motion of small invertebrates was observed in the material. The observer was less than 2 m from the lizard and the scene was clearly visible. The lizard was captured, its sex determined, and released. The anole was a sexually mature female. Upon closer examination, the whitish material was found to be an eggshell, apparently from a bird. An abandoned bananaquit (*Coereba flaveola*) nest

was in the trees above the site. The eggshell was dry, well-fragmented, and obviously not from a recent hatching. No invertebrates were observed on or in the eggshell material. Anoles feeding on ants were seen previously and subsequently, with ants readily observable in the feeding lizard's jaws. Montserrat is an island of volcanic origin and calcium supplementation of the diet for the demands of reproduction may be the origin of this behavior.

Submitted by **PHILIP H. STEVENSON**, 4814 Bromley Lane, Richmond, Virginia 23226, USA

ANOLIS WHITEMANI (NCN). **TAIL AUTOTOMY**. We examined 178 museum specimens (Albert Schwartz Field Series, ASFS, Univ. Kansas Mus. Nat. Hist.; Bobby Witcher Memorial Collection, Avila College; U.S. Natl. Mus., Smithsonian Institution) taken from 21 different sites on Hispaniola and in seven different months. Tails available for examination (many had been lost, presumably during capture) were inspected for indications of breakage and regeneration. The xeric habitats occupied by this anole (O.A.S. 1969. Survey of the natural resources of the Dominican Republic, Study on the development and planning of natural resources. Report of the Technical Assistance Mission to the Dominican Republic carried out by the Natural Resources Unit of the Department of Economic Affairs in 1965-1966. Gen. Secretariat of the Org. Amer. States, Washington, D.C.) and rainfall patterns (Salcedo et al. 1983. Atlas de diagramas climáticos de la República Dominicana. Secretaría de Estado de Agricultura, Sto. Domingo) are very similar at collecting localities. For all statistical tests, a = 0.05.

Seventeen of 98 specimens whose tails were available for examination displayed evidence of autotomy. Frequency of tail loss was higher in females (F: 0.21, n = 43; M: 0.15, n = 55), but not significantly so ($x^2 = 1.28$). There was no significant correlation between SVL and frequency of autotomy (r = 0.11).

Tail autotomy is most commonly associated with predation (Arnold 1988. *In:* Gans and Huey (eds.), Biology of the Reptilia, Vol. 16, pp. 235-273. Alan R. Liss, New York), although Schoener and Schoener (1980. Copeia 1980:839-850) indicated that intraspecific interactions might also be responsible, and that these two factors demonstrate a largely inverse relationship in lizards. In either case, it is expected that males would demonstrate higher frequencies of tail breakage as they are more territorial and, as a result, more likely to be exposed to predation or involved in agonistic intraspecific interactions (Parker and Pianka 1973. Herpetologica 29:143-152). The slightly higher (but statistically insignificant) frequency of autotomy in female *A. whitemani* remains unexplained, as does the lack of correlation with SVL. Larger (= older) individuals would have been expected to demonstrate higher rates of tail loss, merely due to increased opportunities (see Schoener and Schoener, op. cit.).

The overall frequency of autotomy in this species is lower than that reported in most populations of Bahamian anoles (Schoener and Schoener, op. cit.). This may be a result of the arid habitats in which *A. whitemani* is found. The harsh environment could be reflected in lower densities of potential predators. Saurophagous snakes in the genera *Antillophis*, *Hypsirhynchus*, and *Uromacer*, and birds, especially kestrels (*Falco sparverius*), have been collected and/or observed in sympatry with *A. whitemani*, but never in large numbers. Also, the densities of lizard populations are low. In 1990, 24 man-hours of effort were necessary to collect each *A. whitemani* at one study site in Peravia Province; by comparison only 0.25 man-hours were needed to collect specimens of *A. chlorocyanus* at a more mesic site in San Cristobal Province. These lower population densities would probably result in fewer incidents of territorial defense.

We wish to thank Darrel R. Frost and John S. Simmons for providing access to the ASFS at the Museum of Natural History, University of Kansas. George R. Zug and Elyse J. Beldon of the Smithsonian Institution loaned specimens. John S. Parmerlee, Jr., Jaime D. Villa, and members of the Avila College Field Biology classes of 1986, 1988, and 1990 helped in the field. Sixto and Ivonne Incháustegui provided assistance in the Dominican Republic. José A. Ottenwalder of the Parque Zoológico Nacional facilitated opportunities for field work. Permits were graciously provided by Emilio A. Bautista M., Director, Departamento de Vida Silvestre, República Dominicana.

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner) and ***COPHOSAURUS TEXANUS*** (Texas Earless Lizard). **SPIDER PREDATION**. A number of invertebrates are reported to prey on reptiles (see Greene 1988. *In*: Gans and Huey (eds.), Biology of the Reptilia, vol. 16, Ecology B, pp. 1-152. Alan R. Liss, New York; and McCormick and Polis 1982. Biol. Rev. 57:29-58 for reviews). Only a few accounts exist of spider predation on lizards (e.g., Cokendolpher 1977. J. Arachnol. 5:184; Corey 1988. J. Arachnol. 16:392; and Blondheim and Werner 1989. British Herpetol. Soc. Bull. 30:26-28.). We report two instances of predation by araenomorph spiders on juvenile lizards.

On 15 June 1985, one of us (JCG) observed a dead *Cnemidophorus sexlineatus* (SVL = 52.5 mm; AUM 32930) being pulled into a burrow by a lycosid spider, *Geolycosa* sp. The incident took place 7.65 km W of Cannon Town, Okaloosa Co., Florida. The lizard was apparently recently killed and its right eye socket digested.

In the other instance, MKC and MJW observed a *Cophosaurus t. texanus* (SVL = 26 mm, mass = 0.5 g; TCWC 66686) being preyed upon by another lycosid spider, *Arctosa littoralis* (TL = 16 mm, mass = ca. 0.4 g). The incident took place at Lake E. V. Spence, 3.3 km W of Robert Lee, Coke Co., Texas. The lizard had three puncture marks on its throat and a collapsed right eye. The spider was discovered under a rock with the already dead lizard, manipulating it with apparent ease.

In areas of rocky shoreline at Lake Spence, both spiders and Texas earless lizards occur in abundance. In this situation, spider predation on small juvenile lizards might not be a rare event.

We thank J. R. Dixon for comments on this note. We also thank Allen Dean for the identification of *Geolycosa littoralis*.

EUMECES SEPTENTRIONALIS (Prairie Skink). **PISCIVORY**. The prairie skink is a North American lizard characterized by a diet that is primarily insectivorous (Breckenridge 1943. Amer. Midl. Nat. 29:591-606). Fish have not been previously recorded as a food item (reviewed in Somma and Cochran 1989. Great Basin Nat. 49:525-534). On 3 June 1990 be-

tween 0930 and 1030 h, six *Eumeces septentrionalis* (three gravid females, one male, and two juveniles) were captured from amongst riprap and beneath stone slabs on the earthen dam forming the windward shoreline of Burchard Lake, Pawnee Co., Nebraska (T.12N., R.10E., Sec. 4). The three females and one juvenile were placed in the same collecting bag. Within ca. 1 h a large fecal pellet was found in the bag. It contained the remains of a small fish (probably a cyprinid), represented by numerous small (ca. 2 mm diam), cycloid scales, two fin rays, and one partially digested amphicoelous vertebra. It was not possible to determine which lizard excreted the pellet.

Prairie skinks in this population feed largely upon the numerous roaches (*Blatta* sp.) and crickets (*Gryllus* sp.) which live beneath the riprap and flat limestone rocks upon the dam (pers. observ.). The rocks and riprap also provide shelter for the skinks, including nest sites for brooding females (Somma 1990. Bull. Chicago Herpetol. Soc. 25:77-80). The insects are attracted to left-over food and bait discarded by fishermen. It is likely that the ingested fish was discarded bait left on the dam or was washed ashore with the wind-blown drift (dead vegetation, invertebrates, and fish) as carrion.

Active foraging for fish in the water has only been described in a few species of lizards including *Varanus indicus*, *V. mertensi*, *V. mitchelli*, *V. semiremex* (Cogger 1986. Reptiles and Amphibians of Australia. 4th ed. Reed Books, Sydney) and *Shinisaurus crocodilurus* (Schmidt and Inger 1957. Living Reptiles of the World. Doubleday & Co., Garden City. 287 pp.). While aquatic behavior has been observed in southern populations of *E. septentrionalis*, it only occurred as a form of escape behavior (Taylor 1935. Univ. Kansas Sci. Bull. 23:1-643; Black 1975. Herp. Rev. 7:111). It is unlikely that this terrestrial lizard actively forages in the water. Fish, in the form of dropped food and other nest spillage, constitute half the diet of the Seychelles skinks, *Mabuya seychellensis* and *M. wrightii*, living among breeding colonies of Lesser Noddies (*Anous tenuirostris*) on Cousin Island (Brooke and Houston 1983. J. Zool. (Lond.) 200:179-195). It should not be surprising that skinks eat fish when available as carrion, in light of the fact that they are considered intensive foragers that rely on both visual and chemical cues to detect prey (Regal 1978. In Greenberg and MacLean (eds.), Behavior and Neurology of Lizards, pp. 183-202. Natl. Inst. Mental Health, Rockville, Maryland; Huey and Pianka 1981. Ecology 62:991-999; Vitt and Cooper 1986. J. Herpetol. 20:408-415). Thus, the probability that the fish in this observation was eaten as a result of opportunistic scavenging upon carrion seems the most parsimonious explanation. While this is the only recorded instance of a North American skink eating fish, it is probable that this behavior occurs, albeit infrequently, in other populations of skinks living along shoreline habitats.

I thank D. Ferraro, D. Lokke, J. Lokke, and J. Young for their invaluable assistance in the field. The manuscript was greatly improved by the proofreading and criticism of J. M. Matter.

SCELOPORUS UNDULATUS (Prairie Lizard). **RAFTING**. Although oceanic rafting of terrestrial organisms has been documented (Carlquist 1965. Island Life. Natural HIstory Press, Garden City, New York; Schoener and Schoener 1984. Oecologia 63:289-294), there are no published accounts of rafting on freshwater systems. The genetic constitution of individual populations and the distribution of organisms on the mainland may be significantly affected by rafting of individuals between populations or to new locations. For example, Smith (1946. Handbook of Lizards. Comstock Publ. Assoc., Ithaca, New York. 542 pp.) proposed that downstream transport of northern prairie lizards (*Sceloporus undulatus garmani*) on floating logs or other debris may account for the expansion of their range eastward in Kansas and Oklahoma. Seasonal rains in Oklahoma often flood the shores of rivers and streams. The propensity of *S. undulatus* for log piles (Ferguson et al.

Publication Announcement

THE REPTILES AND AMPHIBIANS OF THE CIMARRON NATIONAL GRASSLANDS, MORTON COUNTY, KANSAS

Joseph T. Collins & Suzanne L. Collins

with Photographs by the Authors

This booklet defines the reptile and amphibian diversity of the Cimarron National Grasslands, and includes accounts of the 31 species known to reside there. The text accounts contain standard common names, characteristics, size and size maxima, habits and habitats, when the species was first discovered in the Grasslands, current abundance, and reproduction and food preferences. The introduction contains a summary of herpetological explorations in Morton County, a checklist of the herpetofauna, and remarks on their threatened status. A complete bibliography is included. There are 32 color photographs of amphibians and reptiles, and eight color photographs which display the rugged beauty of this wilderness area in extreme southwestern Kansas. *viii + 60 pages, 40 color photographs, 3 figures. January 1991.*

Price $7.00 postpaid. Make checks payable to U. S. Forest Service. Orders may be sent to U. S. Forest Service, Cimarron National Grasslands, 242 Highway 56-E, P. O. Box J, Elkhart, Kansas 67950 USA.

This publication financed and co-sponsored by

1983. *In:* Huey et al. (eds.), Lizard Ecology, pp. 134-148. Harvard Univ. Press, Cambridge, Massachusetts) enhances the probability of dispersal by rafting in this species during floods. Here we present evidence of such dispersal by *Sceloporus undulatus* in Oklahoma.

Two adult *Sceloporus undulatus*, one male (SVL = 51 mm, TL = 125.5 mm) and one female (SVL = 50 mm, TL = 129.5 mm) were recovered from a log floating down Pennington Creek in Tishomingo, Johnston Co., Oklahoma on 4 April 1989. The water level in the creek was elevated ca. 2 m above base flow due to recent rains. The log, ca. 2 m long by 40 cm diam, was first observed floating towards a dam ca. 3 m in height. The log floated over the dam and was submerged for 10 sec in the pool below the dam. At this time the two *S. undulatus* were captured and both survived in captivity for several weeks following rescue. In addition to these lizards, at least two other lizards were noted scrambling about a mass of logs and other debris that had accumulated below the dam. Although we were unable to catch these lizards for measurements, their presence adds support to the hypothesis that downstream transport in *S. undulatus* may be common. If rafting occurs frequently, not only will it serve as a mechanism for transporting organisms to new locations, but it will also facilitate gene flow between populations.

We thank T. Heger and D. Hillis for comments on the manuscript.

SERPENTES

AGKISTRODON PISCIVORUS CONANTI (Florida Cottonmouth). **FORAGING BEHAVIOR**. A snake's tail can be used for a variety of functions. For instance, the tail can be used to anchor the animal is it descends from basking sites in trees (Burkett 1966. Univ. Kansas Publ. Mus. Nat. Hist. 17(9):435-491). On 27 September 1989, 12 October 1989, and 30 October 1989, an adult female cottonmouth (ca. 105 cm TL) was observed in close proximity to a 32 m drift fence array on Eglin Air Force Base, Okaloosa Co., Florida. On two occasions, I observed the snake hook its tail and posterior one-third of its body around half of the top of the pitfall bucket and lower itself into the bucket. Thus anchored, the snake swirled its head around in the debris in the bottom of the bucket several times as if searching for prey items; however, I did not observe the capture of any prey.

Hooking the tail on the bucket rim allowed the bulky snake to effectively search the bucket for prey (238 amphibians and reptiles were caught in nine months of survey at this location). Mammals and birds have been documented predators on animals falling into pitfall traps, but this is the first recorded instance of a cottonmouth systematically and repeatedly searching pitfall buckets. Although *Masticophis flagellum* has been observed to anchor its body with its tail during ambush (Jones and Whitford 1989. Southwest. Nat. 34(4):460-467), my observations appear to be only the second instance of a snake employing its tail to anchor the body while foraging.

I wish to thank Howard Kochman and Paul Moler for reviewing this manuscript. I would especially like to thank C. Kenneth Dodd, Jr., without whose assistance this work would not have been possible.

Submitted by **KARL R. STUDENROTH**, P.O. Box 1194, Melrose, FL 32666, USA

BOTHROCHILUS PAPUANUS (Papuan Olive Python). **KERATOPHAGY**. *Bothrochilus papuanus* is now known to exhibit ophiophagic tendencies both in the wild (O'Shea 1988. Herp. Rev. 19(2):36) and in captivity (Boos 1983. ASRA Journal 2(1):28; B. W. Tryon, pers. comm.). During July 1990 a large specimen (2 m+), in the process of sloughing its skin while maintained in a relatively restricted glass aquarium at the National Museum of Papua New Guinea, was observed to undergo ecdysis and then devour a section of its own sloughed skin. The snake was healthy and well fed so such behavior may suggest that this species is potentially cannibalistic.

Submitted by **MARK T. O'SHEA**, 46 Buckingham Road, Penn, Wolverhampton, WV4 5TJ, England, and **ILAIAH BIGILALE**, National Museum of Papua New Guinea, Waigani, NCD, Papua New Guinea

CHONDROPYTHON VIRIDIS (Green Tree Python). **COMBAT FATALITY**. Numerous accounts of combat behavior between male snakes have been reported, although no record exists of combat-related mortality. Four animals (two males, two females) were housed together in an enclosure measuring 90 x 90 x 150 cm. Numerous branches were available so no two snakes had to share the same branch. The snakes were misted daily. On 2 May 1990, the two males were observed in combat. The combat behavior resulted in moderately severe lacerations to both individuals. They were promptly removed from the enclosure, the lacerations were sutured, and the snakes housed individually. The sutures were removed on 21 June 1990. The lacerations had healed with no infection noted.

On 7 September 1990, the two males were reintroduced to the enclosure housing the females. On 2, 10, and 11 November 1990, the males engaged in combat. They were allowed to remain together, with the hopes that the dominant male would breed with the females. On the morning of 12 November 1990, the males were observed coiled around each other on the enclosure floor. Closer inspection revealed that one of the individuals was dead.

The gross necropsy of this animal revealed numerous lacerations on the skin as well as a six-inch long hemorrhagic area along the neck. The pathologist determined that there was no evidence of preexisting disease in this snake, and that trauma was the most likely cause of death. The carcass will be deposited at Louisiana State University.

Submitted by **JANICE PERRY-RICHARDSON**, Audubon Park and Zoological Garden, P.O. Box 4327, New Orleans, LA 70178, USA

CONTIA TENUIS (Sharptail Snake). **PREDATION**. On 30 March 1986 at 1030 h, one of us (BT) found a DOR adult western toad (*Bufo boreas*) with an adult *Contia tenuis* (also dead) protruding from its mouth. Both appeared to have been run over by a vehicle the previous evening. The location was in the Sierra Nevada foothills near Penryn, Placer Co., California. The specimens were not collected.

A recently-ingested adult *C. tenuis* was found in the stomach of a brook trout (*Salmo fontinalis*) collected 18 June 1983 in Providence Creek ca. 4.8 map km WSW Dinkey Ranger Station, T.10S., R.25E., Sec. 23 (NE corner), ca. 1600 m elev., Sierra National Forest, Fresno Co., California. The trout was collected via electroshocking during a survey of fish populations by California Department of Fish and Game biologists B. Ehler and R. Goss. The preserved *Contia* is in the collection of RWH and will be deposited at MVZ.

LOXOCEMUS BICOLOR (Burrowing Python). **FEEDING BEHAVIOR**. This neotropical snake is primarily fossorial and presumably nocturnal (Mora 1987. J. Herpetol. 21:334-335). Little information is available about its diet. Greene (1983. Amer. Zool. 23:431-441) found two teiid lizards and two rodents in the stomach of museum specimens and Mora (op. cit.) and Mora and Robinson (1984. Rev. Biol. Trop. 32:161-162) reported that *L. bicolor* feeds on reptile eggs and described egg-eating behavior. Additional information on its constricting behavior in the laboratory was reported by Willard (1977. Copeia 1977:379-382) though the prey item was not specified. Here I report that this species also depredates hatchling iguanids. The observations were conducted at the Dr. Rafael Lucas Rodríguez National Wildlife Refuge (Palo Verde), Costa Rica (10°21' N— 85°21' W).

Ctenosaur (*Ctenosaura similis*) and iguana (*Iguana iguana*) hatchlings excavate a narrow tunnel to facilitate their exit from the nest at the beginning of the rainy season (Mora 1989. Herpetologica 45:293-298). Three *L. bicolor* were observed at night in exit tunnels. On 6 May 1986, one *L. bicolor* (ca. 1 m TL), was observed half way in the exit tunnel of a ctenosaur nest. When removed, the snake held a hatchling ctenosaur in its mouth and when palped, at least two more hatchlings were in its stomach. The other two snakes were observed on 8 May and 9 May, in nests of ctenosaurs and iguanas, respectively; neither snake could be captured.

I thank M.I. Di Mare and C. McDonough for their comments on the manuscript. Financial and logistical support was provided by the World Wildlife Fund, Organization for Tropical Studies, and the Subdirección de Vida Silvestre de Costa Rica.

Submitted by **JOSÉ M. MORA**, Welder Wildlife Refuge, P.O. Box 1400, Sinton, TX 78387, USA ●

STORERIA OCCIPITOMACULATA OCCIPITOMACULATA (Northern Redbelly Snake). **BEHAVIOR**. Jordan (1970. Herpetologica 26:466-468) found captive *Storeria o. occipitomaculata* stiffening and feigning death when attacked. Vogt (1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Publ. Mus., Milwaukee. 205 pp.) reported that although he had handled hundreds of *S. occipitomaculata*, only once did he encounter an individual which seemed to feign death. That individual, found on a cold day in May, became stiff and was able to be held erect like a match stick. In this note I report a dissimilar death feigning behavior of wild *S. o. occipitomaculata*.

On a warm day in May 1988, when I captured an individual (ca. 8 cm SVL) on a gravel road near Sturgeon Bay, Door Co., Wisconsin (T.28N., R.26E., Sec. 29), it ceased moving and its body became flaccid. As I held the limp snake in my open palm, it rolled its head to one side and exhibited the lip flaring display described by Gosner (1942. Copeia 1942:181-183). After several minutes of inactivity, the snake started to crawl out of my hand. When I caught it with my other hand, its body again went limp. The snake was placed on the road and after a short period of immobility, it crawled away.

Later that evening, when a second *S. o. occipitomaculata* was picked up, it also ceased moving and did not try to escape. When placed on the ground it crawled away. The air temperature was considerably cooler than in the previous encounter. Neither of the snakes I observed stiffened their bodies while feigning death.

I thank P. A. Cochran for comment on an early draft of this note.

THAMNOPHIS SIRTALIS PARIETALIS (Red-sided Garter Snake). **POPULATION MORPH VARIATION**. Over the past five years, we have captured unusual color morphs of the red-sided garter snake, *Thamnophis sirtalis parietalis*. These morphs include melanistic individuals as well as individuals lacking the dorsal and lateral stripes; having no red or yellow coloration; or lacking either the dorsal or lateral stripes (Fig. 1). All individuals were collected at overwintering hibernacula located on small islands in Lake Winnepegosis, Manitoba, Canada. As these populations are comprised of only an estimated few hundred individuals, the relative proportion of these unusual morphs is estimated to be significant.

The reproductive isolation of these populations appears to be substantial. Interestingly, individuals on these islands migrate by swimming to the mainland after spring emergence and return to the islands in the fall to hibernate. It is not known if all the snakes leave the islands. In one case, the snakes must swim up to two miles across open water to reach the nearest shoreline. How members of these island populations can locate and return to these islands in the fall is unknown.

Members of these populations are an interesting natural experiment. No melanistic morphs have ever been reported from mainland populations in Manitoba. This suggests an interesting population genetics phenomenon, perhaps a founders effect. Because the islands are relatively small they present an ideal model system for field studies on the genetics of populations and island biogeography.

Finally, as pointed out by King (1988. Herpetologica 44:451-458), melanistic morphs may be especially susceptible to collection because of their unusual appearance and greater commercial value. At present, the ecological impact of continued collecting on these islands is unknown. However, collecting there during spring or fall aggregations would be expected to dramatically affect morph frequencies owing to the relatively small population sizes.

Figure 1. Color variation in individual *T. s. parietalis* collected on islands in Lake Winnipegosis, Manitoba, Canada. A typical member of this species (left), an individual lacking yellow lateral stripes and red side blotches (center), and a melanistic morph (right).

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19: 1–41), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author — curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 3: 802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full — spell out state names — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. All specimen identifications *must* be verified by another authority (not one of the authors). Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to: Joseph T. Collins or Darrel Frost, Section Co-editors, Museum of Natural History — Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454 USA. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic Distribution: *Lampropeltis triangulum multistriata*. SSAR Herp. Review 25: 198.

CAUDATA

Especially For *Herpetologists!*

THE SNAKES OF THAILAND AND THEIR HUSBANDRY

by Merel J. Cox
Orig. Ed. 1991 564 pp. $69.50

ISBN 0-89464-437-8

Here is a well-written aid for both the amateur and professional herpetologist in the identification and husbandry of the snakes of Thailand. The first part is concerned with general aspects of husbandry and also offers specific suggestions regarding the care of snakes native to tropical Thailand. Climatic data for all regions of Thailand are offered and suggestions are made for their application to the care of Thai snakes. The second part of the book focuses on each of the snakes that is known to inhabit Thailand. The coloration, pattern, scale counts, diets and food preferences, natural habitats, and, wherever possible, the breeding habits of each are described. Specific suggestions are made for the care and housing of each genus and, in many cases, for individual species. A total of 164 color photographs, including 115 individual species and sub-species, are included. Also, a series of 36 detailed drawings highlight the characteristics of head scalations of 33 different Thai snakes.

HANDBOOK OF ALLIGATORS AND CROCODILES

by Steve Grenard
Orig. Ed. 1991 $29.50

ISBN 0-89464-435-1

A species-by-species account of alligators and crocodiles covering all known living species and sub-species, this book includes valid, popular, and local names, with discussions on current controversies over nomenclature. It also collates and reports data from each state agency in the U.S. on the American alligator, and reports on the status of the Fish and Wildlife Service's American Crocodile Recovery Plan. Included is an extensive resource list, and a bibliography of cited as well as noncited references.

When ordering, please add $4.00 for first book, $2.00 each additional for shipping

MCZ 115793. All verified by Robert Jones. New state records confirming the prediction of Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana State Univ. Press) of distribution along the loess bluff into the Florida Parishes of Louisiana based on Delcourt and Delcourt (1975, American Midl. Nat. 94 (2):385-400).

Submitted by **JAMES LAZELL**, The Conservation Agency, 6 Swinburne Street, Jamestown, RI 02835 and **THOMAS MANN**, Mississippi Museum of Natural Science, Jackson, Mississippi 39202. ●

BUFO DEBILIS (Green Toad). COLORADO: Baca Co: Picture Canyon, Sec. 7, T35S R47W. 12 June 1988. G. A. Hammerson. Verified by Hobart M. Smith. UCM Zoology Color Slide 41. First record for county; fills hiatus between previous records in southwestern Kansas (Collins 1982, Amphibians and reptiles in Kansas. Univ. Kansas Mus. Nat. Hist. 356 pp.) and southeastern Colorado (Hammerson 1982, Amphibians and reptiles in Colorado. Colorado Div. Wildl., Denver. 131 pp.; Livo 1988, Herp. Rev. 19:61).

Submitted by **GEOFFREY A. HAMMERSON**, The Nature Conservancy, 46 Kelsey Street, Middletown, CT 06457, **LARRY VALENTINE**, 1157 Highway 65, Eckert, CO 81418, and **LAUREN J. LIVO**, 1215 South Osceola Street, Denver, CO 80219. ●

BUFO PUNCTATUS (Red-spotted Toad). COLORADO: San Miguel Co: 2 km W Dolores River bridge on Colo. Rt. 141, vic. Slick Rock, southwestern corner of T44N R18W. 17 June 1988. G. A. Hammerson. 1.3 km E Dolores River bridge on Colo. Hwy 141, Sec. 32, T44N R18W. 17 June 1988. G. A. Hammerson. UCM Zoology Color Slide 42. Verified by Hobart M. Smith. First records for county (Hammerson 1982, Amphibians and reptiles in Colorado. Colorado Div. Wildl., Denver. 131 pp.).

Submitted by **GEOFFREY A. HAMMERSON**, The Nature Conservancy, 46 Kelsey Street, Middletown, CT 06457, **LARRY VALENTINE**, 1157 Highway 65, Eckert, CO 81418, and **LAUREN J. LIVO**, 1215 South Osceola Street, Denver, CO 80219. ●

BUFO VALLICEPS (Gulf Coast Toad). USA: MISSISSIPPI: Wilkinson Co: 10.5 km (by road) W Lessley. 10 July 1987. D. A. Rossman, P. A. Myer, and R. Driesbach. Verified by D. A. Good. LSUMZ 47101. New county record and the first record from southwestern Mississippi. Extends range ca. 25.5 km NNW nearest Louisiana locality (Dundee & Rossman, 1989, The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press).

Submitted by **DOUGLAS A. ROSSMAN**, Museum of Natural Science, Louisiana State University, Baton Rouge, LA 70803. ●

PSEUDACRIS CLARKII (Spotted Chorus Frog). USA: NEW MEXICO: Colfax Co: 6.4 km ESE Cimarron. 15 July 1963. Ray D. Burkett. Verified by Joseph T. Collins. KU 78132. This specimen represents a new state record and extends the range ca. 325 km west. Tinkle and Knopf (Herpetologica 20(1):42-47) report a single specimen (TTU 916) from adjacent Bailey County, Texas, 15.2 mi NW Sudan.

Submitted by **CHARLES W. PAINTER**, Endangered Species Program, New Mexico Department of Game and Fish, Villagra Building, Santa Fe, NM 87503, and **RAY D. BURKETT**, Department of Natural Sciences, Shelby State Community College, P.O. Box 40568, Memphis TN 38174-0568. ●

PSEUDACRIS FERIARUM FERIARUM (Upland Chorus Frog). USA: VIRGINIA: Henry Co: 0.1 km E Chatmoss area, jct SR 777 & SR 620. 7 September 1991. T. D. Schwaner. Verified by J. T. Collins. Virginia Museum of Natural History (VMNH R184). New county record.

Submitted by **TERRY D. SCHWANER** & **JOHN M. ANDERSON**, Virginia Museum of Natural History, Martinsville, VA 24112. ●

RANA SYLVATICA (Wood Frog). USA: VIRGINIA: Henry Co: 0.1 km E Chatmoss area, jct SR 777 & SR 620. 5 September 1991. T. D. Schwaner. Verified by J. T. Collins. Virginia Museum of Natural History (VMNH R176-177 & KU Color Slide 8915). New county record.

Submitted by **TERRY D. SCHWANER** & **JOHN M. ANDERSON**, Virginia Museum of Natural History, Martinsville, VA 24112. ●

SPEA INTERMONTANA (Great Basin Spadefoot). COLORADO: Moffat Co: 1.6 km E jct. county roads 4 and 88, T12N, R93-94W. 14 June 1990. G. A. Hammerson. UCM 56222. 3.8 km W jct. county roads 4 and 88, T12N, R94W. 14 June 1990. G.A. Hammerson. UCM 56223-56225. All verified by Hobart M. Smith. Identification based on examination of frontoparietal bones and fontanelle (Zweifel 1956, Am. Mus. Nov. 1762:1-45). Fills large hiatus between previous Colorado and Wyoming records (Hammerson 1982, Amphibians and reptiles in Colorado. Colorado Div. Wildl., Denver. 131 pp.; Baxter and Stone 1985, Amphibians and reptiles of Wyoming. Second edition. Wyoming Game and Fish Dept.).

Submitted by **GEOFFREY A. HAMMERSON**, The Nature Conservancy, 46 Kelsey Street, Middletown, CT 06457, **LARRY VALENTINE**, 1157 Highway 65, Eckert, CO 81418, and **LAUREN J. LIVO**, 1215 South Osceola Street, Denver, CO 80219. ●

TESTUDINES

APALONE SPINIFERA (Spiny Softshell). USA: WISCONSIN: Brown Co: Fox River, below De Pere dam, W shoreline just downstream from Nicolet Paper Company, De Pere (Sec. 21, T23N, R20E). 31 May 1988. H. Quinlan. Verified by P. A. Cochran. University of Wisconsin-Green Bay Richter Collection (0320). Adult male and female collected in fyke net. First record for Brown County and first published record for Fox River drainage below Lake Winnebago (Vogt, 1981, Natural History of Amphibians and Reptiles of Wisconsin, Milwaukee Public Mus. 205 pp.). That *A. spinifera* is not a recent arrival is suggested by a preserved specimen in the St. Norbert College teaching collection labeled "Fox River-1938"; however, severe pollution may have eliminated or reduced populations until water quality improved in recent years. Collection of a juvenile (carapace length 69 mm) on 28 September 1989 indicates that the population is reproducing.

Submitted by **P. A. COCHRAN**, Division of Natural Science, St. Norbert College, De Pere, WI 54115. ●

KINOSTERNON FLAVESCENS (Yellow Mud Turtle). COLORADO: Yuma Co: 12.5 km S, 1 km W Idalia. 10 July 1987. L. J. Livo. Verified by Hobart M. Smith. UCM Zoology Color Slide 52. Confirms presence in S. Republican River drainage, where a single previous record was based on an undocumented (but reliable) observation in the 1970s (Hammerson 1982, Amphibians and reptiles in Colorado. Colorado Div. Wildl., Denver. 131 pp.).

Submitted by **GEOFFREY A. HAMMERSON**, The Nature Conservancy, 46 Kelsey Street, Middletown, CT 06457, **LARRY VALENTINE**, 1157 Highway 65, Eckert, CO 81418, and **LAUREN J. LIVO**, 1215 South Osceola Street, Denver, CO 80219. ●

TERRAPENE CAROLINA (Eastern Box Turtle). USA: MARYLAND: Worchester Co: Assateague Island National Seashore (38°12'15"N, 75°08'40"W). 14 September 1990. Terry D. Schwaner. Verified by J. T. Collins. Virginia Museum of Natural History (VMNH photograph R180 & KU Color Slide 8916). First verified record for the island. Jack Kumer, National Parks Service, stated that a NPS employee had unwittingly introduced several adult box turtles to the park area in the early 1970s. This may account for a reported observation by Lee (1973, Bull. Maryland Herp. Soc. 9:110-111). The new record is a juvenile (carapace length = 92 mm; 4-5 growth rings on a costals), which suggests that the introduced population may be reproducing.

Submitted by **TERRY D. SCHWANER** & **JOHN M. ANDERSON**, Virginia Museum of Natural History, Martinsville, VA 24112. ●

LACERTILIA

ANOLIS PORCATUS (Cuban Green Anole). DOMINICAN REPUBLIC: DISTRITO NACIONAL: Aeropuerto Internacional de "Las Americas." 20 January 1991. R. Powell and J. S. Parmerlee, Jr. Verified by D. D. Smith. Bobby Witcher Memorial Collection (BWMC 04369), Avila College, Kansas City. Two juvenile males were observed in a brief survey of shrubs and trees immediately adjacent to the terminal building. This represents the first Dominican record of this introduced species outside of Santo Domingo and adjacent suburbs (Powell et al., 1990, Amphibia-Reptilia 11(4):421-425) and is over 20 km E of the nearest published locality (Powell, 1990, Herp. Rev. 21(4):96). Extensive efforts during 1990 to find the species in intervening areas were fruitless, indicating that the airport population is probably allopatric to other Dominican *A. porcatus* and most likely represents a separate introduction, either from Santo Domingo or Cuba.

Submitted by **ROBERT POWELL** & **JOHN S. PARMERLEE, JR.**, Department of Natural Sciences, Avila College, Kansas City, MO 64145. ●

CNEMIDOPHORUS SEXLINEATUS SEXLINEATUS (Six-lined Racerunner) USA: TEXAS: Van Zandt Co: 34 km SE Canton off FM 279 at Edom. 25 April 1991. D. K. Bibb. Verified by Stanley E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 17590). New county record filling a hiatus between Henderson, Kaufman, and Smith counties (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station, Texas, 434 pp.).

Submitted by **CHRIS T. MCALLISTER**, Renal-Metabolic Lab (151-G), Department of Veterans Affairs Medical Center, 4500 South Lancaster Road, Dallas, Texas 75216 and **D. KEITH BIBB**, 906 South Cedar Hill Road, Cedar Hill, TX 75104. ●

EUMECES OBSOLETUS (Great Plains Skink). TEXAS: Runnels Co: Lake Moonen, 9.6 km W Ballinger. 27 June 1989. Troy D. Hibbitts. Verified by James R. Dixon. TCWC 66911. A juvenile caught at boat ramp. County record.

Submitted by **TROY D. HIBBITTS**, Department of Wildlife and Fisheries Science, Texas A&M University, College Station, TX77840. ●

EUMECES SEPTENTRIONALIS OBTUSIROSTRIS (Southern Prairie Skink) USA: OKLAHOMA: Major Co: Newton Ranch, SW of St. Rt. 281 (Sec. 19, T22N, R15E). 23 April 1990. T. Anton and G. Moore. Verified by J. T. Collins. KU 217162–163 + KU Color Slides 8876-77 (2 specimens). New county record.

Submitted by **THOMAS G. ANTON**, 1020 Grove Street, Apt. #406, Evanston, IL 60201 & **GARY MOORE**, Route 2, Box 20, Wellston, OK 74881. ●

GAMBELIA WISLIZENII (Longnose Leopard Lizard). COLORADO: Mesa Co: 4.6 km by road NW Colo. Rt. 141 at Gateway, Rd. 4.1, Sec. 34, T15S, R104W, west side of Dolores River. 19 June 1988. G. A. Hammerson. UCM Zoology Color Slide 43. Verified by Hobart M. Smith.

TWO NEW BOOKS ON MIDDLE EAST HERPETOLOGY

•from the Society for the Study of Amphibians and Reptiles•

The Snakes of Iran by Mahmoud Latifi

English translation of 1985 edition in Farsi, covering biology, venoms, and snake bite and its treatment. Descriptive account with information on size, diet reproduction, habitat, and distribution for each species. Key to the 60 species of Iranian snakes, a list (by province) of distribution in Iran, and an extensive bibliography. The 24 color plates include two maps and 22 plates of snakes (66 figures) with range maps. New appendix by Alan Leviton and George Zug contains supplemental bibliography and current nomenclature.

Specifications: 164 pages, 24 color plates, 2 maps, 25 figures (8 photos), 6 x 9 inches, $22 clothbound and postpaid in USA. **Now Published!**

Herpetofauna of Iraq, Kuwait, and the Arabian Gulf Region
by Alan E. Leviton, Steven C. Anderson, Sherman A. Minton, and Kraig Adler

Handbook for identification of amphibians and reptiles of region extending from Turkish border through Iraq, Kuwait, and northern and eastern Saudi Arabia, including the Arabian (Persian) Gulf and lowlands bordering it (southwestern Iran, Bahrain, Qatar, and United Arab Emirates). Book contains checklist of 144 species and subspecies, including diagnosis and distribution, and an illustrated key. The 32 color plates (210 photos) depict every genus and most species. Separate chapter on venomous snakes with section on venoms and treatment. Extensive bibliography of Middle East herpetology and appendix by John E. Simmons on collecting and preservation techniques.

Specifications: About 175 pages, 32 color plates, many maps and text figures, 7 x 10 inches, $28 clothbound and postpaid in USA. To be published shortly.

Send Orders To: Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, MO 63103, USA. Make checks payable to "SSAR."Overseas postage extra.
SSAR membership details are available on request to Dr. Aldridge.

First records for state in Dolores River drainage (Hammerson 1982, Amphibians and reptiles in Colorado. Colorado Div. Wildl., Denver. 131 pp.).

BOTHROPS ALTERNATUS (URUTU). BRAZIL: GOIAS: Município Rio Verde: BR060, Sítio Buriti. 31 May 1988. Benedito

BRANTA BOOKS
P. O. BOX 3457
ANN ARBOR, MI 48106, U.S.A.

We are pleased to note that we have acquired from John Wiley & Sons, Inc. all rights, as well as the residual stock, of volumes

BIOLOGY OF THE REPTILIA

14 (Development A), 15 (Development B), and 16 (Defense and Life History)

These volumes are now listed at the substantially reduced price of $40 each for volumes 14 and 15, and $45 for volume 16 (plus $5 each volume for postage and handling).

Price is based on assumption that check will be included with order. Checks will be returned once stocks are exhausted.

Subsequent volumes are being published by the University of Chicago Press.

Flávio de Andrade. Universidade Católica de Goiás (UCG 2004); Município Jataí: BR 060, 0.5 km N jct. of BR 364, within city limits. Chácara do Alemão. 11 June 1990. Hans Norbert Rubly. UCG 4442; Município Jataí: BR 364, 50 km W Jataí at junction of GO 050. Fazenda Querência. 8 August 1990. Arismildo Martins Fonseca. UCG 4532. All verified by William W. Lamar. New state record, extending known range northwestward over 170 km from closest published locality. The presence of *Bothrops alternatus* has been reported in the surrounding states of Minas Gerais and Mato Grosso do Sul, and from the southeastern region of Brazil. The above three records are the first reported for the southern state of Goiás. This species was expected, but unknown, until these collecting efforts. This region is part of the upper Paraná River basin, sharing some geographical features with eastern Mato Grosso do Sul, and western Minas Gerais and São Paulo, where *Bothrops alternatus* is widely distributed.

Submitted by **GEOFFREY A. HAMMERSON**, The Nature Conservancy, 46 Kelsey Street, Middletown, CT 06457, **LARRY VALENTINE**, 1157 Highway 65, Eckert, CO 81418, and **LAUREN J. LIVO**, 1215 South Osceola Street, Denver, CO 80219. ●

ADDITIONAL DEPARTMENTAL RECORDS FOR THE HERPETOFAUNA OF HONDURAS

Over a span of fourteen years, distributional treatments have appeared for the amphibians, non-snake reptiles, and snakes of Honduras (Meyer and Wilson, 1971, 1973, and Wilson and Meyer, 1985, respectively). During the same time and beyond, field work has continued in the country, resulting in the accumulation of a number of departmental records, some of which have been previously reported (Hahn, 1971; Hahn and Wilson, 1976; O'Shea, 1989; Wilson, Myton, and Cruz, 1976; Wilson, McCranie, and Porras, 1979). We have accumulated a substantial amount of new such records between and including 1979 and 1989. We anticipate the preparation of new, expanded treatments of the amphibians and non-snake reptiles (Wilson and McCranie, in prep.), but because the appearance of these works may come several years in the future, we feel it worthwhile to present these records now as an aid to other workers in the field. Recent snake records supplementing those in Wilson and Meyer (1985) are also included. The records detailed below are arranged according to department. All specimens were collected by at least one of the authors, except where noted. Vegetational formations (Holdridge, 1967) are given when representing the first record for a given species in that formation in Honduras. Other comments are given where appropriate.

DEPTO. ATLÁNTIDA

Eleutherodactylus ridens. Quebrada de Oro, 820-880 m. Subtropical Wet Forest formation. 17 May 1988. Field Museum of Natural History (FMNH) 236380. Extends range about 185 airline km. west of only previously known Honduran locality (Meyer and Wilson, 1971).

Rana maculata. Quebrada de Oro, 820-880 m. 18 May 1988. FMNH 236382.

Sceloporus malachiticus. Cordillera de Nombre de Dios, S slope Cerro Búfalo, 1780 m. 2 June 1980. University of Kansas Museum of Natural History (KU) 194320.

Hydromorphus concolor. Quebrada de Oro, 900 m. 22-23 May 1988. FMNH 236400-01.

DEPTO. CHOLUTECA

Gymnophthalmus speciosus. Vuelta de las Viejas, Punta Ratón. No date. Gustavo Cruz. KU 216146.

Rhinoclemmys pulcherrima. 1.6 km N Cedeño. 13 August 1985. KU 209310.

DEPTO. COLÓN

Bolitoglossa mexicana. Mountains behind Trujillo, 230-250 m. 18 June 1989. FMNH 236378.

Eleutherodactylus noblei. Mountains behind Trujillo, 460 m. 19 June 1989. Tropical Moist Forest formation. KU 214778.

Ptychohyla merazi (tadpoles). Mountains behind Trujillo, 460 m. 19 June 1989. Tropical Moist Forest formation. FMNH 236385.

Coniophanes bipunctatus. 2.9 km S Puerto Castillo, near sea level. 21 June 1989. FMNH 236396.

Leptodeira septentrionalis. Mountains behind Trujillo, 460 m. 19 June 1989. FMNH 236403.

DEPTO. COMAYAGUA

Plectrohyla guatemalensis. Montaña de Comayagua, above Río Negro, 1640 m. 4 May 1982. KU 209683-84.

Sceloporus malachiticus. Montaña de Comayagua, Cerro Volcán, 1750 m. 29 July 1980. Northwestern State University of Louisiana (NSU) 5242-43.

DEPTO. COPÁN

Agalychnis moreletii. Laguna del Cerro, 770 m. 7 August 1982. KU 200526-28.

Centrolenella fleischmanni. Laguna del Cerro, 770 m. 10 August 1982. KU 200525.

Hyla bromeliacia. Quebrada Grande, 1330 m. 10 August 1982. FMNH 236384.

Phrynohyas venulosa. Copán. 13 May 1985. Gustavo Cruz. KU 209307.

Anolis laeviventris. Quebrada Grande,

Ecotour Expeditions

Ecotour is offering a special herpetological study expedition to the lowland rainforest of Amazonia Ecuador to be conducted between August 20th - Aug 31st, 1991. We will focus on the nocturnal fauna of one of the most species-rich regions in the Amazon Basin.

The expedition will be led by an herpetologist with extensive field experience in the Ecuadorian Amazon. We offer full stateside administrative assistance, have all the necessary equipment and staff in Ecuador, and provide complete logistical support.

For information on this expedition or our other expeditions and group programs, phone or write: 800-688-1822, 617-876-5817;

Ecotour Expeditions
P. O. Box 1066
Cambridge, MA 02238

1480 m. 6 May 1988. FMNH 236388.

Anolis lemurinus. La Playona, 180 m. 11 May 1988. FMNH 236390-91.

Sceloporus malachiticus. Quebrada Grande, 1260 m. 8 August 1982. KU 200570.

Clelia clelia (hemipenes only, adult discarded). Laguna del Cerro, 770 m. 10 August 1982. FMNH 236395.

Porthidium nummifer. Below Quebrada Grande, ca. 1300 m. 21 July 1983. KU 203011.

Sibon nebulatus. La Playona, 180 m. 11 May 1988. FMNH 236412.

Tantilla taeniata. Above Quebrada Grande, ca. 1600 m. Lower Montane Wet Forest formation. 6 May 1988. FMNH 236413. The highest previously recorded elevation for this species was 1000 m (Wilson, 1982). The pale middorsal stripe is confined to the middorsal scale row, a condition heretofore unrecorded for this species (Wilson, 1982). The pale nuchal band is divided medially.

Urotheca elapoides. Quebrada Grande, 1370 m. Lower Montane Wet Forest formation. 4 May 1988. FMNH 236406.

Depto. Cortés

Anolis laeviventris. Cerro Cusuco, 1550 m. Lower Montane Wet Forest formation. 21-22 May 1980. KU 194277-85.

Gymnophthalmus speciosus. Santa Elena, 716 m. 6 February 1980. Louisiana State University Museum of Zoology (LSUMZ) 38853.

Mesaspis moreletii. Cerro Cusuco, 1720 m. Lower Montane Wet Forest formation. 2 August 1982. KU 200587-88. First Caribbean versant record for Honduras (Meyer and Wilson, 1973).

Drymarchon corais. Cerro Cusuco, 1550 m. Lower Montane Wet Forest formation. 4 August 1987. FMNH 236398.

Depto. El Paraiso

Bufo luetkenii. Near Ojo de Agua, 665 m. 10 August 1985. KU 209260-61.

Bufo marinus. Near Ojo de Agua, 665 m. 10 August 1985. KU 209263.

Hypopachus variolosus (tadpoles). 18.6 km NW Mandasta, 1435 m. 12 August 1985. FMNH 236379.

Physalaemus pustulosus. Near Ojo de Agua, 665 m. 10 August 1985. KU 209281.

Gymnophthalmus speciosus. 30.6 km NW Mandasta, 1500 m. 12 August 1985. KU 209314.

Leptodeira annulata. 11.1 km SSE Villa San Francisco, 710 m. 11 August 1985. KU 209329-30.

Depto. Francisco Morazán

Thamnophis fulvus. Cerro Cantagallo, 1840 m. 16 August 1985. KU 209349.

Depto. Intibucá

Ptychohyla spinipollex. Zacate Blanco, 2010 m. 17 June 1980. KU 192897-98.

Mesaspis moreletii. Zacate Blanco, 2103-2271 m. 31 January 1980. LSUMZ 38826-27.

Sceloporus variabilis. Ca. 15 km E La Esperanza, 1490 m. 19 June 1980. KU 194331-33.

Drymarchon corais. 2.7 km N Jesús de Otoro. 29 January 1980. Louis Porras. LSUMZ 38830.

Depto. La Paz

Eleutherodactylus rugulosus. ca. 7 km S Marcala, 1540 m. 22 June 1980. KU 195553.

Depto. Lempira

Plectrohyla guatemalensis. Naranjos, above Villa Verde, Cerro Celaque, 1930-1940 m. 25 April 1982. KU 209663-65, 209700.

Ptychohyla spinipollex (tadpoles). Above Villa Verde, Cerro Celaque, 1480 m. 28 April 1982. KU 216145.

Anolis crassulus. Naranjos, above Villa Verde, Cerro Celaque, 1960 m. 25 April 1982. FMNH 236387.

Mesaspis moreletii. Cerro Celaque, E slope, 2530 m. 26 April 1982. KU 200586.

Sceloporus malachiticus. Cerro Celaque, E slope, 2530 m. 26 April 1982. KU 200562.

Crotalus durissus. La Campa. 8 May 1985. Gustavo Cruz. KU 209358.

Ninia sebae. Above Villa Verde, Cerro Celaque. 6 August 1985. KU 209332.

Depto. Ocotepeque

Ninia sebae. Río Chiquito, 6.0 km W La Labor, 1460 m. 12 August 1987. FMNH 236404-05.

Depto. Olancho

Plectrohyla guatemalensis. Sierra de Agalta, 1000 m. Subtropical Wet Forest formation. 8 August 1986. KU 209686.

Anolis laeviventris. Sierra de Agalta, 1470 m. 5 August 1986. FMNH 236389.

Sceloporus malachiticus. Sierra de Agalta, 1470 m. 5 August 1986. FMNH 236392.

Bothrops asper. Sierra de Agalta, 1060 m. 10 August 1986. FMNH 236415.

Clelia clelia. Sierra de Agalta, 990 m. 11 August 1986. FMNH 236394.

Dipsas bicolor. Sierra de Agalta, 1000 m. Subtropical Wet Forest formation. 7 August 1986. FMNH 236397. Extends range about 120 airline km. north of locality of only previously known Honduran specimen (Wilson and Meyer, 1985).

Drymobius chloroticus. Sierra de Agalta, 1000 m. 7 August 1986. FMNH 236399.

Imantodes inornatus. Sierra de Agalta, 990 m. Subtropical Wet Forest formation. 6 August 1986. FMNH 236402.

Scaphiodontophis annulatus. Sierra de Agalta, 1000 m. 7 August 1986. FMNH 236410.

Sibon dimidiata. Sierra de Agalta, 990 m. 9 August 1986. FMNH 236411.

Depto. Valle

Rana berlandieri complex La Orilla, ca. 3.5 km S Amatillo. 11 March 1988. FMNH 236383.

Anolis sericeus. Isla Zacate Grande. 25 June 1980. KU 194287.

Sceloporus squamosus. Isla Zacate Grande. Tropical Dry Forest formation. 25 June 1980. KU 194329.

Agkistrodon bilineatus. San Lorenzo. No date. Gustavo Cruz. FMNH 236414. First mainland record for Honduras. Recorded from Isla Zacate Grande, Depto. Valle by Cruz et al. (1979).

Crotalus durissus. 3.7 km N San Lorenzo. 14 August 1985. KU 209357.

Depto. Yoro

Celestus bivittatus. Montaña de Macuzal, above El Portillo, 1590 m. Lower Montane Wet Forest formation. 6 July 1983. FMNH 236386. First Caribbean versant record for Honduras (Villa and Wilson, 1988).

ACKNOWLEDGMENTS

We would like to offer our gratitude to the people who worked in the field with us to collect the material herein reported, including G. A. Cruz, M. R. Espinal, H. E. Lawler, L. Porras, and G. E. Schuett. We

also wish to thank W. Aguilar, G. A. Cruz, and M. R. Espinal for their assistance in securing collecting permits from the Departamento de Recursos Naturales Renovables during the years 1979-1989.

BOOK REVIEW

Life History and Ecology of the Slider Turtle, by J. Whitfield Gibbons (with 31 other contributors), 1990. Smithsonian Institution Press, 470 L'Enfant Plaza, Suite 7100, Washington, D.C. 20560 (send orders to Dept. 900, Blue Ridge Summit, PA 17294). xiv + 368 pp. $60.00 + shipping.

This book is the culmination of 20 years of research on turtle biology at the Savannah River Ecology Laboratory (SREL), part of the U.S. Department of Energy's Savannah River Plant (SRP) in South Carolina. The driving force behind this project is Whit Gibbons, who has been associated with SREL since its inception and now serves as its senior ecologist. Fifteen of the 24 chapters are authored in whole or in part by researchers who were at SREL at the time of writing. The book features the yellow-bellied slider (*Trachemys scripta scripta*), but many readers familiar with the primary literature emanating from SREL over the last two decades will not be surprised to find research on other turtle species liberally discussed and/or referenced throughout the text. This is a technical book, and the content is explicitly empirical. It is well-bound and well-printed, and its format (8 1/2 x 11 inches) makes it easy to read. Collecting the bibliography in one place at the end of the book also facilitates use.

The book is organized into six more-or-less coherent sections. Section 1 contains three introductory chapters authored by Gibbons, the last in collaboration with J. D. Congdon. The essence of the first chapter is a series of testable hypotheses concerning the movement and energy allocation patterns of turtles, reflecting in part the unavoidable *a posteriori* nature of the analyses of a project of this magnitude and duration. I liked the ecological definition of a population presented here, emphasizing as it does the stochastic influences of the local environment on parameters delimiting one. Two unique features included in this chapter are comprehensive appendices on SREL turtle publications and Ph.D. dissertations on turtles, respectively.

Chapter 2 describes in detail the physical features of SRP as they pertain to the subject matter, and provides a delightful series of anecdotes and descriptions of the research and habitats involved which are particularly entertaining for anyone who has worked on similar long-term projects and/or with government agencies. I was confused by the statement that SRP was acquired from "public lands" in 1951, and infer that since 30-40% of SRP was once farmland that acquisition and/or condemnation of private lands was involved.

Chapter 3 emphasizes the utility of turtles in studying the evolution of life histories in long-lived iteroparous organisms. Gibbons and Congdon are able to provide a unique cautionary perspective from long-term studies on turtles of the extreme variability in life-history parameters within species' populations exposed to different environments, between different species exposed to the same or similar environments and between the sexes in the same species.

Section 2 contains 4 chapters which serve to illustrate the still problematic phylogenetic relationships among and nomenclatural status of slider turtle populations, and the techniques which can be brought to bear on these problems. Ernst provides a concise, cogent exposition of the taxonomic history of emydine turtles, and accepts the *Chrysemys-Pseudemys-Trachemys* arrangement first proposed by Agassiz and most recently codified by Seidel and Smith (1986). He recognizes five species of *Trachemys*, and 14 subspecies within the sole mainland species *scripta*. Seidel and Jackson also accept Agassiz' arrangement but suggest that the precise phylogenetic relationships among contemporary emydine genera are far from clear. They indicate that fossils assignable to *Trachemys* may be as old as 7 million years, and that some subspecific differentiation among mainland *scripta* may be traceable in Pliocene fossils. Legler, however, does not recognize the Agassiz split and considers *scripta* a polytypic species of *Pseudemys* (*sensu lato*) with 17-18 subspecies, describing two as new herein. I found Legler's thorough discussion of the biogeography and phylogenetic relationships among slider populations particularly enjoyable, providing much fodder for future work, although some of the scenarios he rejects seem no more arbitrary than those accepted. All three of these chapters strongly suggest that the potential for recognition of multiple species within *scripta* is high. Smith and Scribner provide a succinct and

very interesting exposition of extremely high levels of genetic differentiation among and between populations of sliders on SRP, noteworthy again because of the long-term nature of the study and the high mobility of these turtles. This chapter has important implications for elucidating the effects of selection in a highly dynamic, unpredictable habitat mosaic on the genetic structure of long-lived, late-maturing animals.

Section 3 presents six chapters on reproduction and growth, perhaps the most interesting of which is the exhaustive review and synthesis by Congdon and Gibbons on the biology of turtle eggs. They point out an interesting difference between species with flexible-shelled and rigid-shelled eggs; eggs of the former type are developmentally sensitive to the hydric environment of their incubation medium and this leads to differences in the selection regimes experienced by turtle species depending on which egg type they possess. In addition, concepts of parental investment have to be modified for turtles since energy stores are apportioned between two separate processes, embryogenesis and fueling the hatchling after hatching. The hatchlings of many turtle species overwinter in the nest, and a wide variety of parental investment strategies of energy allocation ensue.

The following chapter by Gibbons and Greene present a wealth of data on clutch frequency, size and age at sexual maturity and other parameters for *T. scripta* and other SRP turtle species, and once again highlights the importance of long-term studies as key to the understanding of life-history evolution. It turns out that male *T. scripta* on SRP reach sexual maturity at a certain size whereas females reach sexual maturity at a specific age; however, complex interactions with other life-history parameters render these demographic determinations imprecise. Similarly, interactions between clutch size and other morphological and environmental characteristics complicate a direct positive relationship between female body size and clutch size. The most confusing chapter of this book is the one by Dunham and Gibbons on growth. It contains a pedestrian review of techniques for the measurement of size and analysis of growth, and concludes with a discourse upon factors affecting growth which have very little to do with turtles. Whereas it seems clear that indeterminate growth occurs in SRP *T. scripta*, it is unclear whether differences in growth rates exist between the sexes. The authors state (p. 139) that "the two sexes grow at the same absolute rate before and after reaching the asymptote..." and (p. 141) "...the absolute growth rates of females must be significantly higher than those of males in all populations." The confusion perhaps results from the lack of a clear exposition of what the two free parameters of the growth models they employ mean biologically in this case.

The three remaining chapters discuss slider populations from other areas. Mitchell and Pague support the relationships of size to reproductive characteristics and patterns of growth developed for SRP *T. scripta* for populations in southeastern Virginia. Moll and Moll provide a nice table summarizing reproductive data for neotropical slider populations (which they refer to as *Pseudemys scripta*). They conclude that any differences in reproductive (or other ecological) characteristics between temperate and tropical populations are ones of degree, not kind, and directly related to longer growing seasons in the latter habitats. These authors view the reproductive ecology of sliders as an exaption which, along with a certain degree of habitat alteration, allowed these turtles to successfully invade the tropics. Vogt provides limited data to suggest that the critical temperature for producing males in tropical Mexican populations of *T. scripta* is 1°C lower than that for temperate populations, and speculates that nests of the former are actually experiencing lower temperatures in nature. He contravenes without supporting evidence the conventional wisdom and considerable data suggesting that size determines sexual maturity in female sliders. The population Vogt studied appears to be heavily skewed towards adults, and he attributes this to heavy predation, especially by *Crocodylus moreleti*. The abundance of juvenile *Staurotypus triporcatus*, a sympatric bottom-dwelling species, is cited as evidence to suggest that it is not nest predation which is responsible for the skewed population structure of *Trachemys*. This observation only allows inference concerning the relative effects of nest predation on *Staurotypus* and, without additional data, allows no discrimination between the effects of distinct avenues of predation on the demography of the slider population in question.

Section 4 contains a set of six chapters relating in diverse ways to the demography of and interactions between slider populations. In the initial chapter Gibbons discusses somewhat redundantly how the assessment of sex ratios in turtle populations is complicated by trapping and sampling biases, differential seasonal activity and mobility between the sexes, and interpopulational variation in movement patterns. One of the most important questions raised, yet to be adequately addressed with data, is whether or not females in species with temperature sex determination manipulate sex ratios by behavioral means to conform with Fisher's theory of parental investment in the sex least costly to produce and in shortest supply. Arguably the most important chapter in this book follows in which Frazer, Gibbons and Greene employ a wealth of excellent data to construct a complete life-table for *Trachemys scripta* on SRP. They provide a first-class review of survivorship in turtle eggs and hatchlings, and re-emphasize the challenges to accurate evaluation of life-histories in long-lived, iteroparous species in which individual females do not reproduce annually but continue to harvest and expend energy. I can recall few such quality treatments in animal ecology (certainly only Don Tinkle's work on *Uta* in herpetology) and I expect this one to become a classic in the field.

The remaining chapters in this section are all interesting. Gibbons, Greene and Congdon provide a qualitative characterization of movement patterns in turtles and an assessment of associated selective benefits and risks. They make the curious assertion that individual female sliders leave aquatic habitats on SRP and travel in the same general direction overland on consecutive nesting forays because "... a nesting individual would be expected to follow a known route that resulted in her own survival and a satisfactory nest on a previous occasion..." without defining the latter statement or indicating how it would be assessed. Colonization by sliders of newly-constructed farm ponds in Mississippi reported by Parker (using *Pseudemys* as the generic name) reveals that most colonizers are immature animals. Population turnover in these habitats remained higher than for nearby established ponds throughout the study, growth rates were slower, and population densities and biomass remained lower. Schubauer, Gibbons and Spotila compared home ranges of *T. scripta* estimated by mark-recapture methods and radiotelemetry on SRP and found that the latter method yielded areas that were significantly larger for both sexes. Most of the increase was due to the land portion of the home range. Home range size was significantly correlated with body mass for females and with the length of time monitored for males. The final chapter in this section by Lovich, McCoy and Garstka is a discussion of melanism in *T. scripta*. The

effect of melanism on turtle taxonomy is reviewed. The onset of melanism in male sliders is not strictly dependent on age, size, or the attainment of sexual maturity. A comprehensive study of steriod metabolism in this species demonstrated significant differences between melanistic and non-melanistic individuals and suggests to the authors a direct albeit not exclusive connection to melanophore action and melanin deposition. The direct action of steroids at the level of gene expression was not investigated, however. A thoughtful discussion on the adaptive significance of melanism ensues and the suggestion is made that melanism serves as an important visual cue in social interactions.

Section 5 contains four chapters on bioenergetics. Parmenter and Avery provide a standard review of the feeding ecology of *T. scripta*, emphasizing that the nutritional requirements for the species are largely unknown. They state (p. 264) that effects of temperature on growth rates and the attainment of sexual maturity are unknown while citing (p. 266) several studies on increased temperatures promoting growth in this species, and ignoring the studies which have demonstrated a positive relationship between size and sexual maturity in female sliders. Hinton and Scott contribute a particularly interesting chapter on the use of radioisotopes in ecological research, not the least because of the lengthy sponsorship of SREL activities on SRP by the Department of Energy and its predecessors. A very useful discussion of radionuclide kinetics, which must be understood in at least a general way to make their use and interpretation in radiobiology meaningful, serves as the basis of the chapter. Although of greatest utility in metabolic studies, the potential of radioisotopes in chelonian biology remains largely untapped. Spotila, Foley, and Standora develop a climate space model based on various biophysical parameters thought to influence thermoregulatory behavior of *T. scripta* which was found to adequately predict such behavior in two aquatic habitats on SRP. The remarkable capacity of this species to survive long periods of underwater winter dormancy via altered physiology is noted. The final chapter in this section by Esch, Marcogliese, Goater, and Jacobson is a unique review of the taxonomy and phylogenetic relationships of helminth parasites and turtle hosts and the potential uses of these parasites as indicators in turtle biology. Data from turtles on SRP support the hypothesis that a correlation exists between local habitat stability and parasite numbers and species diversity. The authors make a clear case that the distribution and abundance of parasites in turtles is a potentially very useful tool for attaining a deeper understanding of several aspects of host biology, such as the ontology of diet and feeding behavior, seasonal movements, and zoogeography.

The final section of this book contains a single chapter by Gibbons which serves as an epistle on the value of long-term ecological research. The turtle research at SRP has provided the critical data needed to address biological questions such as the ontology of reproduction in long-lived species, indeterminate growth in reptiles, sex ratios in vertebrates, and the effects of long-term variability in environmental parameters on demographics of natural populations.

I found almost no typographical or other errors in this book. The most noteworthy are in Chapter 5, where the *Chrysemys nelsoni* species account published in the Catalogue of American Amphibians and Reptiles is erroneously attributed to "Herpetological Circulars," a completely different series published by SSAR. Also, two citations by the same author, *a* & *b* in the text, are reversed in the bibliography. If I have to find fault with this book, my major criticism would be that it contains no explicit review of the conservation status of slider turtle populations, although Chapters 4, 7, and 11 briefly touch upon certain aspects of this issue. Evidence of a largely circumstantial nature has been accumulating for some time that certain populations, particularly *T. s. elegans* in Louisiana, are threatened, leading to a recent petition to include this taxon in Appendix II of CITES (Dane, 1989) which was unsuccessful. These threats include the annual replacement of turtle farm breeding stocks with up to an estimated 100,000 adult turtles from wild populations, removal of an additional estimated 765,000 wild-caught turtles for human consumption, habitat destruction, and worldwide introduction of sliders with unforeseen biological consequences into areas where they are not native (Warwick et al. 1990). This book would have been the ideal opportunity to focus this issue and bring it to the attention of the people who are likely to be most interested.

This is an important book, and likely to remain a classic of its kind for some time to come. I highly recommend it, despite the price, to anyone interested in turtles or in long-term ecological research in general. The book is a superb summary of ecological research on turtles and will prove especially valuable to those without the opportunity to become intimately familiar with the primary literature in the field, and belongs in every well-equipped science or general library for that reason alone. Those people who denigrate descriptive biology, or who despair about the future of science that is not explicitly directed at *a priori* hypothesis testing, need only read this book to discover how valuable such endeavors really are.

PUBLICATION RECEIVED

Lizards of the Genus *Emoia* (Scincidae) with Observations on Their Evolution and Biogeography, by Walter C. Brown. 1991. Memoirs of the California Academy of Sciences Number 15. The California Academy of Sciences, Scientific Publications, Golden Gate Park, San Francisco, CA 94118, USA. ISBN 0-940-228-24-6. $25 + $2.25 s&h (California residents add 6.5% sales tax). vi + 94 pp.

The 72 recognized species of the lizard genus *Emoia* are described, including 13 new species and three new subspecies. Includes a section on Observations on the Evolution, Relationships of Species Groups, and Distribution of Emoia. Numerous black and white photographs of specimens, two color plates of eight photographs each, several range maps.

HERPETOLOGICAL REVIEW

Volume 22 March 1991 Number 1

SSAR BUSINESS

SSAR ELECTION RESULTS

The results of the 1990 SSAR election are as follows:

President-elect.....Edward O. Moll
Secretary.....J. Eric Juterbock
Treasurer.....Douglas H. Taylor
Board - Regular....Louis J. Guillette, Jr.
Board - Regional Societies.....
Stephen H. Hammack

A total of 672 ballots were cast in this election.

The Society extends its congratulations to the new officers, and its gratitude to the Nominating Committee [Carl Gans (chair), Kraig Adler, Robert Gordon, and Martin J. Rosenberg], and SSAR Elector (Ruth M. Zantzinger) for their hard work, and to the outgoing President and Board Members for their service during their terms. ●

1991 SSAR/HL MEETING

The 1991 Joint Annual Meeting of the Society for the Study of Amphibians and Reptiles and the Herpetologists' League will be held at the Pennsylvania State University, University Park, PA, 6 - 11 August. A detailed program and call for papers was mailed in late February to members of both societies. Additional information can be obtained from Linda R. Maxson, Department of Biology, 208 Mueller Lab, Pennsylvania State University, University Park, PA 16802.

Erratum: In the December 1990 issue of *Herpetological Review*, the incorrect days were given for the symposium on "Captive Management and Conservation of Amphibians and Reptiles." This symposium will be held on *Friday* and *Saturday*, 9 -10 August. ●

SSAR COMMITTEES FOR 1990 - 1991

Following the annual meeting in New Orleans, Louisiana, President William Brown appointed the following committees and coordinators for the current year, to report to the Board at the annual meeting at Pennsylvania State University. Individuals with important matters pertaining to the activities of Society committees should contact the relevant committee chair. Addresses for committee chairs and coordinators are included in the inside rear cover of each issue of HR.

Conservation: Dale R. Jackson (Ch.), John Behler, Kurt A. Buhlmann, William E. Cooper, Jr., Nat B. Frazer, Tom R. Johnson, Thomas E. S. Langton, Paul E. Moler, John J. Moriarty

Grants-in-Herpetology: Darrel R. Frost (Ch.), A. Dale Belcher, Maureen Donnelly, Thomas H. Fritz, Jerry Johnson, Michael V. Plummer, Don S. Wilson

Kennedy Student Award: Ken R. Marion (Ch.), David Duvall, Robert E. Gatten, Jr., Joseph C. Mitchell

Long-range Planning: James L. Christiansen (Ch.), Harold A. Dundee, George R. Pisani

Nominating: Margaret M. Stewart (Ch.), Kraig Adler, Carl Gans, Martin J. Rosenberg

Regional Societies: Stephen H. Hammack (Ch.), John J. Moriarty, Louis Porras

Resolutions: George R. Pisani

Zoo Liaison: Ronald R. Goellner

Common and Scientific Names: Joseph T. Collins (Coordinator), Robert L. Bezy, S. Blair Hedges, J.R. McCranie, Peter C.H. Pritchard, David M. Sever

Joint Meeting Coordinator: Joseph T. Collins

Elector: Ruth M. Zantzinger

Translations Coordinator: Randy Krohmer ●

SSAR CONTRIBUTORS

SSAR wishes to recognize the following members who have contributed to the financial resources of the Society for the year 1990. These contributions make it possible for the Society to provide benefits to the membership that otherwise would be impossible. Many thanks.

SSAR SUPPORTS NATIONAL INSTITUTES FOR THE ENVIRONMENT

In response to an appeal to all national biological professional societies from the Committee for the National Institutes for the Environment (NIE), the Board of Directors of SSAR has recently voted unanimously to endorse the proposed NIE and, on behalf of the Society, the following resolution has been sent to the Committee for the NIE in Washington:

Whereas, environmental health must be regarded as seriously as human health;

Whereas, a solid scientific basis is essential for effective programs to protect the environment;

Whereas, there is a need in the United States for a coordinated national program to support fundamental and applied environmental research encompassing a wide variety of disciplines aimed at understanding, preventing, and solving environmental problems:

Whereas, such research is presently uncoordinated and largely underfunded;

Whereas, a consensus is emerging in the scientific community that a government agency that supports mission-oriented competitively-awarded research, analogous to the way that the National Institutes of Health (NIH) supports biomedical research, may be the most appropriate vehicle to encourage, promote, and support environmental research;

Therefore, the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES supports the concept of creating a National Institutes for the Environment and request to participate in the planning and development of such an Institute.

Background Information on the NIE: A proposal to establish an NIE was developed by a committee headed by Dr. Stephen Hubbell of Princeton University and by Dr. Henry Howe of the University of Illinois - Chicago. A non-profit organization, the Committee for the National Institutes for the Environment, has been established to coordinate this effort. The Committee for the NIE has opened a Washington office in the American Institute of Biological Sciences (AIBS) headquarters building in Washington. Director of the Committee is Dr. David E. Blockstein. The Committee for the NIE will spearhead efforts to establish an NIE (for further details, see *Bioscience* 40(8): 567, Sept. 1990).

The committee may be contacted at:

Committee for the National Institutes
for the Environment
730 11th Street NW
Washington, D.C. 20001
TEL: (202) 628-4303 FAX: (202) 628-4311

The NIE proposal is an effort to greatly expand environmental research and education to drive environmental policy through a new funding agency. Of the $9 billion in federal extramural support for science, 11% goes to environmental sciences (broadly defined). This amount could be increased and the results of this research made more applicable to solving environmental problems through an interdisciplinary agency, analogous to the National Institutes of Health. The present proposal is to set up a series of problem-oriented institutes that would support competitively-awarded mission-oriented environmental research. These five institutes would focus on (1) biotic resources, (2) ecosystem management, (3) sustainable resources, (4) changing human environments, and (5) climate change.

Legislation is now pending in Congress to have the National Academy of Sciences (NAS) conduct a study of the NIE concept. The study would evaluate the current state of research and training in environmental sciences in the United States, and would assess how an NIE might be structured to meet those needs. The Committee for the NIE is providing background for these research efforts to be undertaken by the NAS.

The support which SSAR now has given to the Committee for the NIE by endorsing its efforts is only a first step. In addition, we have been asked to join forces with the other two national herpetological societies, the Herpetologists' League (HL) and the American Society of Ichthyologists and Herpetologists (ASIH), to provide data on research in our discipline. Such data would be gathered under recommendations to be developed by a three-way working group representing each society within the herpetological community on the proposed NIE. Merging the herpetological membership lists of the three societies and conducting a national survey have been proposed.

Plans for an NIE are still in an early conceptual stage. As of late August 1990, a number of organizations have endorsed the NIE including: AIBS, American Ornithologists' Union, American Society of Mammalogists, Council of Scientific Society Presidents, Ecological Society of America, Society for the Study of Evolution, and a number of private environmental organizations.

The present announcement is to alert the membership of SSAR on this initiative by the Society. Until a three-way working group is formally established by the three herpetological societies, the Conservation Committees of SSAR and HL will act as conduits for input of suggestions. SYMPOSIUM ANNOUNCEMENT AND CALL FOR PAPERS

The SSAR Conservation Committee is considering sponsoring an Amphibian and Reptile Conservation Symposium at the 1992 annual meeting in El Paso, Texas. Our tentative plan includes a morning session focused on a specific topic such as a taxonomic group (e.g., sea turtles or iguanid lizards), region (e.g., desert, high elevation populations, rain forest), or conservation/management methodology. The committee is interested in co-sponsoring the morning session with persons or organizations involved with the selected topic. The afternoon session would be devoted to a broad spectrum of herpetological conservation and/or management topics. Papers of particular interest are those dealing with "hands on" projects directly related to habitat improvement, mitigation of threats, reproductive enhancement, and restocking or relocation of rare or endangered amphibians and reptiles.

To be considered for participation in the symposium, submit a preliminary abstract by 30 September 1991. Anyone interested in serving as a convener/organizer for the morning session should contact T. Johnson (below) by 30 June 1991, with your ideas.

Final deadline for paper abstracts will be 31 January 1992. Send abstracts or

questions to:

NEWSNOTES

LAUNCHING OF A NEW BOOK SERIES: BIOLOGY OF THE AMPHIBIA

The book series *Biology of the Reptilia*, edited by Carl Gans, is a unique and monumental contribution to herpetology. It presents comprehensive reviews of all aspects of reptilian biology. These are more detailed and more exhaustively documented by literature than is possible in most review articles or than is usually achieved in books. It is an ongoing series with topics treated as sufficient information comes to hand to warrant a review. Now past its 16th volume, it has become the most authoritative single source of information on reptiles that is available. It has been, and continues to be, invaluable to herpetologists.

There is no equivalent reference work for the Amphibia. The book *Biology of Amphibians* (Duellman & Trueb 1986) is an excellent general work, clearly written and well illustrated, and with a remarkable depth and breadth for a single volume. It will be the standard general reference on amphibians for many years to come and the oncoming generation of herpetologists will consider it the "amphibian bible" much as their predecessors regarded G.K. Noble's (1931) *The Biology of the Amphibia*.

However, no single volume fulfills the need for a sequential, monographic treatment of specialized topics. Certain subjects have been covered at levels equivalent to the standard *Biology of the Reptilia* in the three volumes of Physiology of the Amphibia (Moore 1964, 1974; Lofts 1976) and in The *Reproductive Biology of Ampibians* (Taylor and Guttman 1977), but it has now been 26 years since the first of these works and 14 years since the last one and many topics are in need of updating. The forthcoming book *Environmental Physiology of the Amphibians* (Feder and Burggren, in press, University of Chicago Press) will bring some of those topics up to date and treat new ones. Collectively, these works leave large gaps in physiology unaddressed, and there are not equivalent, recent reviews for most other aspects of amphibian biology.

Recognizing that the discipline of amphibian biology has reached sufficient maturity to warrant detailed, multi-volume review and that such a need has only been partly filled, with no committment to continue the process, it was decided to launch a new series: *Biology of the Amphibia.* It is viewed as an ongoing series of multi-authored volumes, to be treated at the same level and with the same degree of comprehensiveness as *Biology of the Reptilia.* The proposed series will not compete with the titles mentioned above. Recently reviewed topics will not be covered in early volumes of the series, but will be reserved for such time as an update is required.

The editor of the series will be Harold Heatwole, assisted by individual co-editors for particular volumes. Michael Tyler and Margaret Davies have agreed to serve in that capacity for one each of projected volumes. The publishers Surrey Beatty & Sons Pty. Ltd., now well known to herpetologists through a number of high quality publications on amphibians and reptiles, have undertaken to launch the series pending review of manuscripts for the first three volumes. Authors have been contacted for some chapters and parts of those volumes are now in preparation.

The purpose of this notice, in addition to announcing the series, is to solicit suggestions and participation by herpetologists. Interested authors should address queries or send titles and tentative outlines of chapters, as well as target dates for completion, to: Harold Heatwole, Department of Zoology, University of New England, Armidale, NSW 2351 Australia. Phone (067) 732468; FAX (067) 711869. This will permit organizing contributions into appropriate volumes and allow planning of a publishing timetable. It is anticipated that the first three volumes will deal with the topics of (1) Sensory Perception and Maintenance Behaviour, (2) Taxonomy, and (3) Osteology. Consequently, contributions in these areas are sought especially. Anyone wishing to nominate a topic on which he or she would be willing to serve as co-editor should do so. ●

MEETINGS

1991 IHS

The 15th International Herpetological Symposium on Captive Propagation and Husbandry will be held 19 - 23 June 1991 in Seattle, WA. Over thirty speakers will present papers on many aspects of amphibian and reptile husbandry and propagation, and six workshops are scheduled on the husbandry and propagation of rare boas and pythons, turtles, tortoises, varanids, other lizards, and amphibians.

For a complete program and registration, contact: IHS, Inc., c/o Brian P. Backner, M.D., 17 Margaret Road, Sharon, MA 02067, USA ●

SYMPOSIUM ON THE TIMBER RATTLESNAKE: CONSERVATION AND PROTECTION

The Massachusetts Audubon Society is planning a day-long seminar on Saturday, December 7 at a location to be announced in Western Massachusetts. The program will include status reports on *Crotalus* populations in New York, New England, and New Jersey and feature conservation methods for this species. A main goal is to consider a petition to have the northeastern population listed as Federally endangered. For further information as it becomes available, send a SASE to: Rattlesnake Symposium, Conservation Department, Massachusetts Audubon Society, South Great Road, Lincoln, MA 01773, USA ●

REGIONAL SOCIETIES

ADDRESS CHANGES

The following address changes or notifications of new societies have been submitted since the list of herpetological societies was printed in the June 1989 issue of *Herpetological Review.* Please make the appropriate changes in your listing of regional herpetological societies.

Arizona Herpetological Association
P.O. Box 39127
Phoenix, AZ 85069-9127, USA

Central Kentucky Herpetological Society
3564 Rockyhill Terrace
Lexington, KY 40517, USA

Hoosier Herpetological Society
P.O. Box 40544
Indianapolis, IN 46204, USA

International Society for the Study of
Dendrobatid Frogs
c/o Ed Tunstall
2320 W. Palomino Drive
Chandler, AZ 85224, USA

New England Herpetological Society
P.O. Box 1082
Boston, MA 02103, USA

New York Turtle & Tortoise Society
163 Amsterdam Avenue, Suite 365
New York, NY 10023, USA

Northern Nevada Herpetological Society
P.O. Box 21282
Reno, NV 89515-1282, USA

Venomous Snake Society
P.O. Box 691454
Los Angeles, CA 90069, USA

Virginia Herpetological Society
c/o Joseph Mitchell
Department of Biology
University of Richmond
Richmond, VA 23173, USA

Wisconsin Herpetological Society
P.O. Box 366
Germantown, WI 53022, USA

Wyoming Herpetological Society
P.O. Box 1907
Casper, WY 82602, USA

Society officers are encouraged to forward to the SSAR Regional Society Liaison (see inside front cover of HR) any address changes for their society. Newly formed societies are invited to announce their existence in this column, and established societies are invited to submit short descriptions of their organization for publication in this column.

IGUANA SOCIETY

The International Iguana Society is a newly formed society whose mission it is to preserve the biological diversity of iguanas. The I.I.S. is a non-profit corporation filed with the Secretary of State of Florida. Membership is open to all persons and institutions interested in the conservation of iguanas. For further information please write to:

The International Iguana Society
Finca Cyclura
Rt. 3 Box 328
Big Pine Key, FL 33043, USA ●

FEATURES

SALINITY CORRELATIONS OF THE LEECH *Placobdella multilineata* ON ALLIGATORS

Leeches reported to occur on the American alligator (*Alligator missipiensis*) include *Placobdella multilineata* from Florida (Forrester and Sawyer 1974; Cherry and Ager 1982), *Placobdella papillifera* from Texas (Smith et al. 1976), and *Philobdella gracilis* from southeastern Louisiana (Viosca 1962). While procuring data on other studies involving the American alligator (Brantley 1989, Platt 1990), we made observations of leech infestation on juvenile, subadult, and adult alligators within an estuarine swamp and marsh between Lakes Pontchartrain and Maurepas in southern Tangipahoa and northern St. John the Baptist Parishes, Louisiana. A salinity and elevational gradient exists in this area, which includes swamps, a marsh-scrub zone with salinities from 0–3 ppt during different times of the year, and an intermediate salinity marsh type zone, where salinities fluctuate between 0 and 5 ppt.

One-hundred and five juvenile (< 1.2 m total length [TL]) and subadult (1.2–1.8 m TL) alligators were hand collected between 13 April and 24 September 1988 (Brantley 1989). An additional 81 subadult and adult (> 1.8 m TL) alligators were collected between 10 and 19 September in the area by hunters. All animals were inspected for ectoparasites externally as well as inside the mouth and cloaca. A relative estimate of leeches present was noted (0 = none; 0–50 = slight; > 50 = heavy). Representative leeches were taken alive to the laboratory for identification. Salinities were recorded at the site of capture using a portable salinity-conductivity-temperature (SCT) meter. Animals collected by hunters were assigned to one of the habitat zones.

Placobdella multilineata was observed on 13 of the 186 (7.0%) of the alligators examined. No other leech species were observed. Most alligators with leeches were collected from the freshwater swamp and no salinities greater than 0 ppt were recorded from any capture location of an infested alligator. Six of the alligators collected in the freshwater swamp along with the single infested alligator from the marsh-scrub zone had slight cases of leech parasitism. The remaining six animals from the freshwater swamp were heavily infested with leeches. *Placobdella multilineata* was observed mostly on the dorsal tail scutes. Other sites of attachment included the head, back, legs, and inside the mouth. No detrimental effects due to leeches were noticed on any alligator. This study suggests that *Placobdella multilineata* cannot tolerate salinities greater than 0 ppt. Since *P. multilineata* is the suspected vector for the blood parasite *Haemogregarina crocodilinorum* in American alligators (Khan et al. 1980), this has significant implications. In coastal areas within the range of the American alligator and in commercial farming of this species, leech and possibly haemogregarine parasitism could be controlled by creating low salinity environments.

ACKNOWLEDGMENTS

This research was supported by the Louisiana State Board of Regents through the Rockefeller Trust Fund. We appreciate the cooperation and assistance of the Louisiana Department of Wildlife and Fisheries personnel, especially Jerry Wagnon and Robert Love. Comments by Robert Hastings and Lance Fontenot greatly improved the manuscript.

SURVIVAL OF BILLBUGS (*Sphenophorus* spp.) EGESTED BY WESTERN TOADS (*Bufo boreas*)

Curculionids (weevils/billbugs) are eaten by toads, but are not always digested. Smith and Bragg (1949) found a small, unidentified weevil that regularly survived ingestion by *Bufo cognatus*; Fair (1969) documented the survival of *S. phoeniciensis* through the digestive tract of *B. boreas*; and Barrentine and Seeno (1988) found that *S. venatus vestitus* survives passage through the digestive tract of *B. boreas*.

The western toad (*Bufo boreas*) is common in suburban central and southern California, where residential landscaping and irrigation practices often provide suitable habitats for survival. Such habitats often include warm season turfgrasses (Beard 1973). Billbugs (Coleoptera: Curculionidae) are known to infest these grasses. In this study I determined the dietary frequency of billbugs (*Sphenophorus* spp.) in Western toads (*B. boreas*) foraging arthropods from a residential lawn, and calculated the survival frequency for egested billbugs.

MATERIALS AND METHODS

Freshly egested fecal pellets were collected from eight Western toads foraging from a 0.06 ha residential lawn (cultivar of *Cynodon dactylin x C. transvaalensis*) in Bakersfield, CA. Pellets were collected daily between 0500-0800 h from mid-June to mid-August of 1987 and 1988. Individual pellets were stored in unsealed plastic vials for four days at 24-28°C and 35-45% Relative Humidity.

Vials were examined twice daily and live (emergent) billbugs were removed and tallied. After four days, pellets were dissected to quantify dead (non-emergent) billbugs. Other prey items found in fecal pellets were not identified in this study.

RESULTS AND DISCUSSION

Billbugs (*S. phoeniciensis* and *S. venatus vestitis*) were present in 87.3% (370) of 424 fecal pellets. A total of 4,406 billbugs were recovered from 370 pellets. Billbug density (number of billbugs per pellet) ranged from 1 to 64; mean density was 11.9 (SD = 12.0, 370). Nearly 68% (2,978) of the 4,406 billbugs emerged unaided from pellets within four days after fecal egestion.

Fair (1969) reported a billbug (*S. phoeniciensis*) survival frequency of 47.2% (17/36) from a sample of six toad (*B. boreas*) fecal pellets. Barrentine and Seeno (1988) found a billbug survival frequency (for mixed *S. phoeniciensis* and *S. ventatus vestitus*) of 62.0% (186/300) for 54 toad (*B. boreas*) pellets. Overall billbug survival frequency in the present study is higher than that reported by Fair and similar to that reported by Barrentine and Seeno. Differences in survivorship frequencies between the three studies may be attributable to differences in survivorship between *Sphenophorus* spp. In this study, no attempt was made to assess survivorship frequencies for *S. phoeniciensis* and *S. venatus vestitus* separately. Further research will address possible differences between these species' survivorship.

Billbug mortality may be due to the effects of mechanical and chemical digestion and/or to the inability to escape entombment from a desiccating pellet. Notably, less than one percent of the dead (nonemergent) billbugs in toad fecal pellets were disarticulated. Billbug survivorship, therefore, appears to be due mostly to post-egestive, rather than pre-egestive, causes. Hence, toads (*B. boreas*) may derive little (if any) nutrition from ingested billbugs.

ACKNOWLEDGMENTS

I thank Terry N. Seeno, Senior Insect Biosystemist, California Department of Food and Agriculture, for confirming the identity of *Sphenophorus* spp. in this study. The helpful comments of anonymous reviewers are also appreciated.

BEHAVIOR OF THE GRAY TREEFROG (*Hyla chrysoscelis*) DURING THE NON-BREEDING SEASON

During the breeding season, male gray treefrogs (*Hyla chrysoscelis)* congregate at breeding sites and vocalize in order to attract gravid females. On such occasions, behavioral observations of this nocturnal species can be made with relative ease (e.g., Godwin and Roble 1983; Roble 1985 *a,b*; Morris 1989; Morris and Yoon 1989; Ritke et al. 1990; Ritke and Semlitsch 1991). After the breeding season most individuals apparently disperse from breeding sites and are, for the most part, non-vocal (pers. obs.). As a result, virtually no information is available regarding the biology of the gray treefrog during this period. We observed the behavior of *H. chrysoscelis* during the non-breeding season, primarily during October and November 1989 at the Memphis State University Meeman Biological Field Station in Shelby Co., Tennessee (see Ritke et al. 1990 for a description of the study site), as part of an ongoing study of this species.

On 1 October an adult male (male #1, SVL = 43 mm, mass = 6.9 g) was found in a knothole cavity of a sassafras tree (*Sassafras albidum*) 1.9 m above ground. On 3 October another adult male (male #2, SVL = 46 mm, mass = 8.7 g) and a

juvenile frog (sex undetermined; frog #3, SVL = 31 mm, mass = 2.4 g) were found in a knothole cavity of an elm tree (*Ulmus* spp.) 5.1 m above ground, submerged in tannin-colored water with their heads protruding above the surface. All three frogs were toe-clipped for later identification. Another adult male (male #4; not measured or marked) was located on 13 October in a third knothole cavity of a sassafras tree 2.5 m above ground. Park et al. (1950) suggested that gray treefrogs may use knothole cavities as resting sites. McComb and Noble (1981) confirmed the use of knothole cavities by gray treefrogs in Louisiana, primarily during the non-breeding season.

During the day at temperatures ≥ 25° C, frogs were observed with their heads protruding from knotholes or sitting on the rims of knotholes. On one occasion (15 October, 1452 h, 30.0° C), male #4 was observed outside his knothole cavity perched on a limb 0.4 m above the entrance to the cavity. These frogs may have been waiting to ambush prey; we once observed (22 Oct. 0343 h, 27.3° C) male #2 leap ca. 0.3 m from his resting position and consume a prey item. After consuming the prey, he returned to his original resting position on the rim of the knothole.

At dusk, frogs emerged from knotholes when temperatures were ≥15.8° C, and assumed the water-conserving position (sensu Ralin 1981) on limbs, usually horizontal and < 2.0 m from their resident knothole cavity. Infrequently, male #2 and frog #3 were observed climbing higher into the canopy until they were lost from view. Our observations revealed that gray treefrogs are "sit-and-wait" predators, remaining motionless on limbs and allowing prey to come within striking distance. After sunset, wood roaches (*Parcoblatta lata, P. uhleriana, Ischnoptera deropeltiformis*) and camel crickets (*Ceuthophilus* spp.) sometimes drink from water-filled cavities. Thus, frogs may be staying near knothole cavities to prey on these and other arthropods that may arrive during the night (see also McComb and Noble 1981). Additionally, remaining near knothole cavities might enable frogs to quickly escape predators.

During the breeding season, male gray treefrogs are thought to be territorial, defending perch sites (locations used to call and attract gravid females) from conspecific males by pushing and shoving intruders (Fellers 1979; Ritke and Semlitsch 1991). The observation of two frogs occupying the same knothole cavity suggests that adult males may not defend daytime resting retreats from other frogs during the non-breeding season and there is evidence that this may also be the case during the breeding season (Swink 1977). Furthermore, on several occasions (e.g., 23 October, 1936 h, 20.9° C), we observed male #2 and frog #3 sitting on the same branch, < 0.50 m apart, without exhibiting any kind of aggression even though the close proximity of both frogs may have resulted in intraspecific competition for food. The non-aggressive behavior of male #2 towards frog #3 may also indicate that adults are more tolerant of younger frogs.

On 18 October (1900 h, 3.8° C) after several days and nights of cold weather (2.0-7.0° C), we observed male #4 nearly buried in moist, organic material in his resident knothole cavity with only a portion of his back and eyes exposed. Male #2 was found in his resident knothole cavity completely submerged in tannin-colored water. On 19 October (1745 h, 6.1° C) and 20 October (1330 h, 11.7° C) both frogs were observed again in their respective cavities. By 21 October (1210 h) the air temperature had warmed considerably (21.4° C) and male #2 was now sitting on the rim of the knothole; male #4 was no longer inside his cavity, his whereabouts unknown.

Frogs were not observed in knothole cavities after mid-November when the mean high temperature for the month was 0.4° C. Thus, gray treefrogs apparently do not use knothole cavities as hibernation sites. On 10 December (1500 h, -0.6° C) an unmarked adult male (not weighed or measured) was found 20 m from the edge of the study site, hibernating under 8 cm of moist sod. During the cold spell of October, daytime air temperatures inside the cavities of the three knotholes ($\bar{X}$ = 5.7° C, SD = 0.74) were not appreciably warmer than air temperatures directly outside ($\bar{X}$ = 5.1° C, SD = 0.95). Thus, frogs would not gain a significant temperature advantage by hibernating inside knothole cavities.

During our searches of the understory and canopy during October, we located two metamorphs from the 1989 breeding season (3 Oct., 1930 h, SVL = 13 mm, mass = 0.2 g; 22 Oct., 2200 h, SVL = 25 mm, mass = 1.6 g). Both frogs were located 3.0 m above ground on a horizontal tree branch with a hollow cavity. The small size and logistics of the entrance to the cavity prevented examination to determine if frogs were using this cavity as a daytime resting site. Roble (1979, 1985*b*) found that metamorphs of gray treefrogs in Wisconsin and Kansas, respectively, rarely ascended into trees to forage prior to their first hibernation. More data are needed to determine if foraging in trees by first-year metamorphs is a general phenomenon at our study site.

It was apparent during this study that gray treefrogs exhibit some degree of site fidelity as they almost always returned to their resident knothole cavity after nightly foraging bouts. Furthermore, on 20 April 1990, male #1 and male #2 were located in the knothole cavities they occupied the previous autumn. These frogs, however, vacated their cavities after the first breeding chorus of 1990 (29 April). For unknown reasons, gray treefrogs did not occupy the knothole cavities observed in this study during the 1989 or 1990 breeding seasons (mid-April to mid-August). It was apparent that males at our study site ascended high into trees (> 8 m) during the breeding season. Thus, the knothole cavities used by gray treefrogs in this study may have been too low to the ground.

ACKNOWLEDGMENTS

We thank Raymond D. Semlitsch for providing encouragement and guidance throughout this study. Sincere appreciation is also extended to Chester R. Figiel, Jr. and Mary E. Jackson for finding the hibernating treefrog, to Robert L. Davidson for identifying the wood roaches, and to Ellen J. Censky, C. Jack McCoy and Mary K. Ritke for greatly improving earlier drafts of the manuscript.

BIOMEDICAL AND SURGICAL ASPECTS OF CAPTIVE REPTILE HUSBANDRY

by Fredric L. Frye

2nd Ed. 1991 $289.50

ISBN 0-89464-310-X

This second edition is enhanced by the addition of much new and previously unpublished information. Two chapters that have been included are written by recognized experts in their fields of interest: Dr. Alex Rubel of Zurich, and Dr. Douglas Mader. Dr. Rubel contributed a monograph on radiography and imaging. Dr. Mader wrote a monograph on antibiotic therapy and discusses the relevance of metabolic scaling of antibiotic dosages. Other chapters include an introduction to herpetology, captive husbandry, a guide to nutrition, infectious diseases, antibiotic therapy, conditions related to the captive environment, radiology and imaging, hematology, non-hemic parasitology, ophthalmic disorders, reproductive disorders, developmental anomalies, anesthesiology, surgery, comparative histology, euthanasia, necropsy techniques, and pathologic conditions. More than 1,800 color photos are included.

A PRACTICAL GUIDE FOR FEEDING CAPTIVE REPTILES

by Fredric L. Frye

Orig. Ed. 1991

ISBN 0-89464-518-8

In this guide, ready sources on alternatives for many dietary items for the feeding of captive reptiles are discussed in detail. In the case of invertebrate prey, practical methods for their culture are provided. Throughout the manual, certain diagnostic methods and treatments will be mentioned and, although the purpose of this guide is to provide the correct diets for a variety of captive reptiles, it is not intended as a do-it-yourself veterinary manual for nonveterinarians. Species lists, cross-indexed both by common name and scientific name, are included, as well as an appendix, glossary, bibliography, an index by name, and general subject index.

When ordering, please add $4.00 for first book, $2.00 each additional for shipping

PSEUDOCOPULATION IN *Lepidodactylus lugubris*

The mourning gecko, *Lepidodactylus lugubris*, is a widespread species that occurs throughout the Indo-Australian Archipelago and Oceania. Because of this species' apparent propensity for colonization, many populations, particularly those of Australia and the islands in the Pacific Basin, have been attributed to either historical or pre-historical human-aided dispersal (Cogger 1985; Gibbons 1985). Probably enhancing this ability to disperse is parthenogenesis (Cuellar and Kluge 1972), a process that potentially allows a single female to be a founder. Ineich (1988) showed that populations of *L. lugubris* in French Polynesia are actually a complex of unisexual clones, bisexuals, and hybrids. Populations of *L. lugubris* on Guam are all parthenogenetic females but are composed of two morphotypes most closely resembling Ineich's clones 'A' and 'C'. In our sample, 76% are the clone 'A' type, and the remainder, clone 'C'. Despite our biological and distributional grasp of *L. lugubris*, few behavioral studies have been conducted. This paper will describe a portion of the behavioral repertoire of clone 'A'.

From November 1988 to July 1990, we observed three species of gekkonids (*Gehyra mutilata, Hemidactylus frenatus,* and *L. lugubris*) in a house in the village of Malojloj, Inarajan Municipality, Guam, Mariana Islands. On 7 August 1989 at 1835 h we noticed three *L. lugubris* in close proximity on an inside wall adjacent to an open window. The largest of the geckos approached and climbed onto the back of a second, orienting itself parallel to the second. No biting was observed and both were tail-waving (Marcellini 1977) . The superior (male-like) individual firmly grasped the inferior (female-like) individual behind the forelimbs with her forefeet. The female-like gecko then raised her tail (still waving) and exposed her vent. The male-like gecko then swung its tail and vent beneath the female-like's and cloacal apposition resulted. This position was held for less than two minutes when we apparently disturbed the behavior by using a flash during photographing. The female-like gecko immediately disengaged and moved several feet away (behind a picture on the wall and probably out of sight of the male-like gecko) and the male-like gecko then displayed apparently at us and assumed and 'arch-back' agonistic stance (Marcellini 1977) at a 90° angle to us. During the entire pseudocopulatory episode, the third individual remained ca. 30 cm from the two pseudocopulators and exhibited tail-waving.

A distinct vocalization was associated with the pseudocopulatory event. Immediately prior to our noticing the three participants, a series of very soft, evenly spaced (about one second interval) "chucks" was heard. These vocalizations continued throughout the pseudocopulatory event but we were unable to discern which of the three geckos was calling. We have also heard these vocalizations in association with four other incidents of intraspecific interactions in which mounting but not pseudocopulation was observed. These latter incidents closely resemble what Werner (1980) termed 'apparent homosexual behavior' and are possibly what Brown and Sakai (1988) observed and regarded as dominance interactions.

Both geckos were collected. The male-like *L. lugubris* (Michael J. McCoid, Private Collection, MJM 1173) had a SVL of 44.1 mm and contained two vitellogenic follicles 5.7 mm diam. The female-like gecko (MJM 1174) was 40.6 mm SVL and contained two non-vitellogenic follicles 1.6 mm diam. Any conclusions on the relationship of ovarian cycle to behavior (Moore et al. 1985) are precluded because of the sample size.

A second pseudocopulation was observed 1 July 1990 at 2000 h. Both geckos appeared to be clone 'A' types but almost immediately disengaged and fled when a light was turned on. Because of the observational brevity of the encounter, neither female was collected and no vocalizations heard. Pseudocopulation has also been observed in other populations of *L. lugubris*. David Crews (pers. comm.) recorded pseudocopulation on Coconut Island, Hawaii and I. Ineich (pers. comm.) observed this behavior in French Polynesia. In two instances, the latter person noted that the pseudocopulators were clone 'A' types.

Pseudocopulation has been documented in other lizards. Crews and Fitzgerald (1980), Moore et al. (1985), and Crews et al. (1986) suggested that pseudocopulation was closely tied to ovarian stage and was hormonally mediated in teiid lizards. They, along with Gustafson and Crews (1981), also suggested that pseudocopulation may enhance egg output. Brown and Sakai (1988) indicated that pseudocopulation may occur in *L. lugubris* and reported a social component to egg production. Recently, Paulissen and Walker (1989) questioned the role of pseudocopulation in teiids and suggested that it may be an artifact of captivity.

While the relationship between pseudocopulation and vocalization may be equivocal, our observations of agonistic interactions (ca. 20 person-hours) did not include the above described call. The only vocalization associated with the agonistic interactions was similar to that described by Marcellini (1977) as Single Chirp and may function as a release or escape call in intraspecific encounters. Since we began this study, ca. 400 person-hours have been invested and only

two pseudocopulatory events observed. Importantly, though, vocalizations similar to those associated with pseudocopulation and mounting can be heard nightly at the study site, suggesting that the relatively rare events observed are, in fact, very common in *L. lugubris*. Our observations, both visual and acoustic, on free-living *L. lugubris* suggest that pseudocopulation may be an important component of the behavioral repertoire of, at least, clone 'A'.

ACKNOWLEDGMENTS

We thank G. Wiles, T. Fritts, and G. Rodda for comments on an earlier version of this paper. Both D. Crews and I. Ineich generously supplied observational data. Research for this study was funded by the Endangered Species Conservation Program, Project E-4.

DANGEROUS TO MAN? A RECORD OF AN ATTACK BY A BLACK CAIMAN (*Melanosuchus niger*) IN GUYANA

The black caiman (*Melanosuchus niger*) is a large crocodilian and the largest of the Neotropical caimans. Verifiable records indicate that this species attains a total length (TL) of at least 4 m, and possibly 5-6 m (MacCreagh 1961; Medem 1981; Thorbjarnarson and McIntosh 1987). Black caiman are distributed throughout the Amazonian drainage, although populations also occur in coastal French Guiana and Guyana, and are classified as endangered throughout all range states (Groombridge 1982). The principal causes of the decline of this species have been unrestricted large-scale hide hunting and the incompatibility with domestic livestock and humans (Plotkin et al. 1983). It is this last aspect, the relative danger to humans posed by the presence of black caiman, that I discuss in this paper.

Although any crocodilian longer than 2 m TL is capable of inflicting serious or fatal wounds to humans, only two of 23 species of Crocodilia are regularly reported as being predators of humans. These are the Nile (*Crocodylus niloticus*) (Graham and Beard 1973) and saltwater crocodiles (*C. porosus*) (Webb et al. 1978). Two additional species, the mugger crocodile (*C. palustris*) (Deraniyagala 1939) and the American alligator (*Alligator mississippiensis*) (Pooley et al. 1989) have also been implicated in attacks on humans. While it is important to recognize the potential for dangerous encounters between most crocodilians and humans, management decisions must be tempered by the probability of such occurrences.

The large size and formidable appearance of adult black caiman have inspired fear and earned them the reputation of being possible predators of humans (Reese 1923; Guggisberg 1972; Caras 1975; Medem 1981; Pooley et al. 1989), although few records of authenticated attacks by this species are available. Thurn (1883:130), commenting on the crocodilians of Guyana, wrote "They are rarely harmful to man, though one occasionally hears stories of how an arm or leg has been snapped off by one of these reptiles....Generally when lying, basking, on the surface of the water the cayman is a sluggish animal, and it is not dangerous to bathe, in shallow water, close by them, if the bather only keeps his eye upon them and is prepared to run as soon as the cayman seems about to move." Bates (1863:294-295) earlier observed black caiman populations at a time of pristine abundance during 11 years of field investigation in the Amazon basin. He remarked on "...the timidity or cowardice of the alligator," stating that "He never attacks man when his intended victim is on his guard; but he is cunning enough to know when this may be done with impunity...." Bates went on to describe how a besotted native, ignoring warnings of the presence of a large black caiman, went to bathe at Caiçara, Brazil, and was promptly seized and drowned by the animal. A second, unsuccessful attack on a young boy that occurred in the 1890s is described by MacCreagh (1961:188-189), who also recounted bathing harmlessly in the presence of black caiman. These are the sole authenticated literature records of attacks by a black caiman of which I am aware aside from the questionable, colorful account of Norwood (1958:192-195, 1960:iv). In a highly adventurous tale reminiscent of Indiana Jones, Norwood describes how his Amerindian guide and solesurviving prospecting companion succumbed to attacks by 'alligators' while thrashing through the swamps delirious and near death from snake bite near the headwaters of the Essequibo River in southcentral Guyana. The stated size of one of the killed 'alligators' was 15', sug-

gesting *M. niger*. While surveying Guyanese caiman populations, I learned of an actual witnessed attack on a human by a black caiman.

In June 1989, I visited Apoteri (4°00'N, 58°36'W), a small (est. pop. about 300) Macusi Amerindian village on the middle Essequibo River, Guyana. While there, I interviewed 18 year old Augustine Alfred who was attacked and badly mauled by a black caiman in the Essequibo River during December 1982 and subsequently lost most of his left arm. Augustine was 11 when the attack occurred; he was bathing and swimming with a friend near shore at dusk. While playing and splashing, his friend dove and grabbed him. Augustine then dove and made a similar gesture toward his friend and surfaced. His friend resubmerged and the next Augustine knew, he was seized on the upper left arm by the caiman and shaken vigorously back and forth. The suddenness of the attack at first led him to think that his friend was again teasing him. Augustine apparently went into an immediate state of shock and didn't remember feeling any pain from the attack, nor were he or other observers able to estimate the size of the caiman. Luckily, his uncle was nearby in a canoe and witnessed what was occurring. His uncle promptly paddled and rammed his canoe into another stationary canoe tethered near the two boys. That action appeared to startle the caiman and it released its hold on Augustine. Augustine was taken to safety and was found to have his upper humerus broken and protruding at both ends and hanging by badly torn flesh. The village radioed for help and Augustine was airlifted the next morning to the public hospital in the capital city Georgetown. Surgeons were unable to repair the damage and amputated the lower 3/4 of Augustine's left arm, after which he spent two months in the hospital recuperating.

Following the attack on Augustine, Apoteri villagers set baited shark hooks and caught and killed about 20 *M. niger* up to 3.7 m TL. Although black caiman had previously taken village dogs at Apoteri and downriver at Kurupukari village, this was the only attack on a human within living memory of village elders. The fact that this instance occurred at twilight and was preceded by raucous splashing undoubtedly contributed to the attack. It is impossible to determine whether the reaction by the caiman was a foraging or territorial defensive response. Certainly the size of a young boy is comparable to the sizes of larger prey items such as fish [e.g., arapaima (*Arapaima gigas*)] or river turtles (*Podocnemis expansa*). However, the incident occurred during the courtship season, and the possibility that the attack was territorial in nature cannot be rejected.

My own experience with wild black caiman indicates that they are most unaggressive compared to other crocodilians and can be readily approached. I was able to census large adult animals (>3m TL) routinely at a distance of 1-2 m in a rubber dinghy, where I was very vulnerable to attack, with no response other than seeming curiosity by the spotlighted caiman. It is this behavior that has historically made black caiman particularly vulnerable to human exploitation (Magnusson 1982).

Is, then, the black caiman dangerous to humans?

Potentially, yes; in reality, no. Even granting imprudent human behavior, the odds of an attack by this species are infinitesimally small. The bad reputation and fear inspired by this species have been unjust and only served to promulgate its demise and counter conservation efforts. The presence, per se, of large adult black caiman in areas inhabited by humans does not warrant the removal of those animals. In localities where *Melanosuchus* populations are recovering the occurrence of a potential nuisance animal near human settlements should be evaluated on an individual basis by pertinent management authorities. Appropriate recommendations include live capture and removal for captive breeding, translocation for restocking, or lastly, selective culling - in that order. The purported incompatibility of black caiman with humans is more perceived than real and should not be accepted as a ruse by hide industry proponents to allow renewed harvesting of this still endangered species. Optional controlled harvest management should be instituted only after well documented population parameters have been studied and the species is accepted by international bodies as no longer endangered.

Publication Announcement

THE REPTILES AND AMPHIBIANS OF THE CIMARRON NATIONAL GRASSLANDS, MORTON COUNTY, KANSAS

Joseph T. Collins & Suzanne L. Collins

with Photographs by the Authors

This booklet defines the reptile and amphibian diversity of the Cimarron National Grasslands, and includes accounts of the 31 species known to reside there. The text accounts contain standard common names, characteristics, size and size maxima, habits and habitats, when the species was first discovered in the Grasslands, current abundance, and reproduction and food preferences. The introduction contains a summary of herpetological explorations in Morton County, a checklist of the herpetofauna, and remarks on their threatened status. A complete bibliography is included. There are 32 color photographs of amphibians and reptiles, and eight color photographs which display the rugged beauty of this wilderness area in extreme southwestern Kansas. *viii + 60 pages, 40 color photographs, 3 figures. January 1991.*

Price $7.00 postpaid. Make checks payable to U. S. Forest Service. Orders may be sent to U. S. Forest Service, Cimarron National Grasslands, 242 Highway 56-E, P. O. Box J, Elkhart, Kansas 67950 USA.

This publication financed and co-sponsored by

U. S. Forest Service ♦ KPL Gas Service ♦ Kansas Department of Wildlife & Parks ♦ Kansas Herpetological Society

A GECKO NEW TO THE UNITED STATES HERPETOFAUNA, WITH NOTES ON GECKOES OF THE FLORIDA KEYS

Human impact on the environment of the Florida Keys has been severe, with extensive destruction or alteration of natural habitats. In spite of this, or perhaps because of it, these islands have proved fertile ground for the establishment of introduced species of lizards of the family Gekkonidae.

Wilson and Porras (1983) listed five species of introduced gekkonids, *Sphaerodactylus argus, S. elegans, Gonatodes albogularis, Hemidactylus turcicus and H. garnotii.* These species have established populations on one or more of the islands comprising the Florida Keys. The Mediterranean gecko, *Hemidactylus turcicus*, confined to edificarian habitat, and the parthenogenetic Indo-Pacific gecko, *H. garnotii*, are probably widespread among those keys linked by the interisland highway. Based on collections made in April of 1989 and 1990, we review the status of populations of *Gonatodes albogularis*, the two introduced and one native species of *Sphaerodactylus*, and report the establishment of a sixth exotic species of gecko on one of the Upper Keys.

The nominate subspecies of the reef gecko, *Sphaerodactylus n. notatus* is native to the south east coastal ridge of mainland Florida and the Florida Keys (Conant 1975; Lazell 1989). Our collections indicate that this species remains common throughout the larger Upper and Lower Keys. In 1989 we collected it on Key Largo (CAS 172078-79), Grassy Key (CAS 172080-82), and on Key West (CAS 172079-102). In 1990 we again collected it on Key West (CAS 174328-29), 174333), on No Name Key (CAS 174324, 174332), and sighted it on Duck Key.

Populations of the ocellated gecko, *Sphaerodactylus argus*, may be in decline. Since first reported from Key West (Savage 1954) there have been only infrequent reports on individual specimens. Wilson and Porras (1983) reported on a specimen collected on Stock Island in 1977, and Love (1978) collected another specimen in Key West. We have failed to collect specimens of this gecko on the Lower Keys.

The ashy gecko, *Sphaerodactylus elegans*, though less common than *S. notatus* in the western Lower Keys, is fairly abundant. We collected *S. elegans* in both 1989 (CAS 172091-92) and 1990 (CAS172330-31) along with *S. notatus* in Key West, on a large vacant lot on US Hwy. 1. In addition to Key West it has been reported from Big Coppit Key (Wilson and Porras 1983), Boca Chica Key (Duellman and Schwartz 1958) and Lazell (1989) lists Summerland Key, Stock Island, Middle Torch Key and Little Torch Key for which museum specimens exist and reports sightings on Cudjoe, Big Pine and Spotswood Keys. In 1990 we also collected this species on Raccoon Key (CAS 174334-36) between Key West and Boca Chicka Key.

The introduced yellow-headed gecko, *Gonatodes albogularis* has only been reported from Key West, and was apparently at one time abundant. However, Wilson and Porras (1983) stated that since 1971 it has become rare with no reported collections since that date. We collected specimens and observed additional individuals in 1989 (CAS172089. 174327) and again in 1990. These collections were made on the same vacant lot noted in the paragraph above.

Crawl Key is located east of Marathon Key and connected to it by the US highway 1 causeway. Most of this small key south of the highway is completely paved. However, a small area (ca. 0.2 ha) of scrubland dominated by Brazilian pepper (*Schinus terebinthifolis*) and Australian pine (*Casuarina equisetifolia*) remains. Two of us (RL and PGF) collected in this area on 20 April 1990, by removing the loose bark from the dead fallen trees, and by turning fallen dead tree trunks, loose rocks and wood trash. We secured five medium sized geckos from beneath these objects and an approximately equal num-

ber evaded capture. The five captures consisted of two non-gravid females (CAS 174852-53), two males (CAS 174850-51), and one female (CAS 174849) containing two large eggs. No other lizards were collected in this immediate area. We did not examine buildings immediately adjacent to our collection site and so cannot say whether this gecko is occupying buildings on Crawl Key. We recognized that these geckoes were probably *Hemidactylus* species but were neither *Hemidactylus turcicus*, nor *H. garnotii*. We later identified them as *Hemidactylus mabouia* (Moreau de Jonnès), a very widely distributed species native to Africa, but found also in the Malagasy Republic, South American and the Caribbean.

In tropical Africa *H. mabouia* is widespread south of the Sahara (Fitzsimons 1943; Kluge 1969). In South America it ranges in a costal belt from Montevideo, Uruguay to Georgetown, Guyana, and from the headwaters of the Amazon river in Peru and Ecuador and throughout its length in Brazil (Kluge 1969). In the Caribbean it is known from all of the larger and many of the smaller islands of the Lesser Antilles (listed in Schwartz and Henderson 1985), in the Greater Antilles it is common on Culebra, Vieques, and Mona Islands, Puerto Rico, and is also found at Guantánamo, Cuba (Kluge 1969, Rivero 1978).

The presence of *Hemidactylus mabouia* in the New World has often been ascribed to human-mediated introductions from Africa during the slave trade. Kluge (1969) provided evidence and argues for natural rafting as the means by which *H. mabouia* colonized South America and the Lesser Antilles. The Greater Antilles populations are probably recent accidental introductions by man. Wilson and Porras (1983) believed that all five previously reported species of exotic geckoes occurring in the Florida Keys arrived in Florida as accidental stowaways during the shipping of plants, produce or other commodities. The presence of *Hemidactylus mabouia* in the Florida Keys is most likely the result of an accidental introduction. Stowage on commercial shipping is not the only possible means of introduction, as pleasure craft frequently ply between the Florida Keys and the islands of the Lesser Antilles. *Hemidactylus mabouia* is common in the Virgin Islands where American registered pleasure craft are likely to call. The location of the Florida Keys population of *H. mabouia* makes its association with pet trade releases improbable.

The common name for *H. mabouia* is the house gecko or tropical gecko. The habitat of *H. mabouia* appears similar throughout its range. On Mona and Culebra Islands, Rivero (1978) found it in warehouses, and under planks, loose rocks, and loose concrete slabs. In Surinam it has been collected from the walls of brick houses and from human habitations in the forest (Hoogmoed 1973). In Africa it has been found in the roofing of native huts, on settlement houses, in hollow trees (Fitzsimons 1943; Pienaar 1978). The habitat in which we collected *H. mabouia* on Crawl Key is entirely in keeping with those reported above. The high density of *H. mabouia* at the Crawl Key collecting site and the presence of a female with well developed eggs suggest that the species is well established in this small area. Further collecting efforts in the surrounding areas will define the range occupied by this lizard in the Florida Keys.

SCALELESS SNAKES AND A BREEDING REPORT OF SCALELESS *Elaphe obsoleta lindheimeri*

Snakes, by definition, are scaled reptiles. Most species possess large symmetrically arranged head scales, small dorsal body scales, and enlarged undivided ventral plates corresponding more or less with the number of vertebrae (Bellairs and Attridge 1975). Because their numbers, shape, and arrangements are fairly constant for each species, scales are used as recognition characters by taxonomists. Specific scale differences are generally assumed to have a heredi-

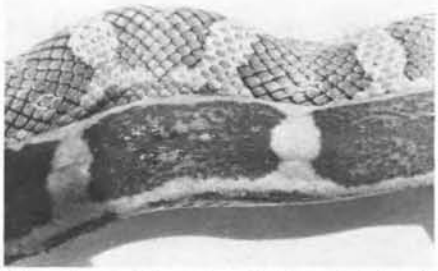

Figure 2. Scaleless rat snake *E. o. lindheimeri* , compared with normal. Dorsal view of body showing vestigial scales.

tary basis, and once fixed during development, scale number and distributions do not undergo further changes (Klauber 1956).

SCALELESS SNAKES

Snakes with anomalous and/or missing scales occur, but attract little notice unless the anomaly is marked or the number of missing scales greatly exceeds normal variation. Several species of snakes with complete, or nearly complete, absence of dorsal scales have been collected. In a *Thamnophis couchi* collected at King's Canyon, CA, the ventrals were reported as undivided (Stickel 1942). A *Pituophis melanoleucus catenifer*, collected near Oakland, CA, had ventral plates that were split into two to four sections (Licht and Bennett 1972). Two *Nerodia sipedon sipedon*, collected in Harford County, MD, possessed ventral scutes (Bennett and Licht 1975). A *Thamnophis sirtalis sirtalis*, collected in Chatham County, GA in 1989, was 584.2 mm long, lacked all dorsal scales, and had normal ventral plates. It is preserved in the Savannah Science Museum collection (R. Moulis, pers. comm.). A juvenile *Lampropeltis calligaster rhombomaculata* was collected in Lafayette County, MA in 1978, and is still living. The ventrals are divided medially by a deep cleft extending the entire length of the body, and the subcaudals are divided and separated (K. Fahey, pers. comm.).

Scaleless snakes have occurred in experimental situations. Albino *Crotalus atrox* in a captive breeding situation at the Atlanta Zoo produced two litters that contained young with no dorsal scales and undivided ventrals. Littermates included normal snakes and snakes with other scale anomalies (D. Herman, pers. comm.). Normal *Elaphe guttata guttata* in a captive breeding situation produced five scaleless young with undivided ventrals, along with normal offspring. All five died before hatching and had other anomalies, including ocular abnormalities and schistosomia (abnormal fusion of the ventral body wall,

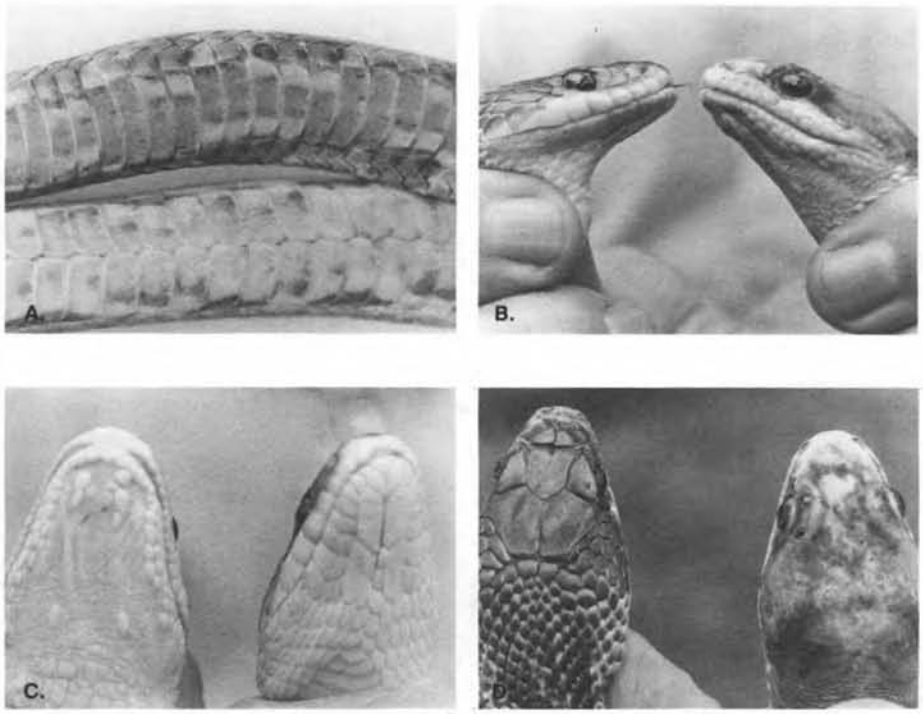

Figure 3. Scaleless rat snake, *E. o. lindheimeri*, compared with normal. A. Ventral scales B. Labials C. Chin D. Top of head.

resulting in doubling over effect) (S. Barten, pers. comm.). Murphy et al. (1987) have summarized literature reports of anomalous scalation patters in snakes.

SCALELESS *Elaphe obsoleta lindheimeri*

In 1985 we obtained a male and female scaleless juvenile *Elaphe obsoleta lindheimeri* on a breeding loan from the Bronx Zoo. The snakes hatched from a clutch of five eggs deposited by one of a group of normal snakes acquired as food for cobras. The other three hatchlings were normal. Collecting data for the mother snake are unavailable. The male scaleless snake survived; the female died of cryptosporidiosis before reaching maturity.

The surviving male snake (Fig. 1) is brick red with smoky black blotches. Aside from tiny partially developed scales scattered over the back and sides, it lacks all dorsal scales (Fig. 2), and the skin is velvety. Any loose skin forms fine wrinkles. The ventral and sub-caudal scales are divided medially by a deep longitudinal cleft (Fig. 3A), resulting essentially in two parallel rows of ventrals the entire length of the body. Occasional ventrals are further broken into several segments, but not divided. Several rows of small irregular upper and lower labials are present (Fig. 3B). The chin is naked except for scattered small irregular scales (Fig. 3C). Aside from two tiny supraoculars on the left side, no scales are present on the dorsal head (Fig. 3D).

In 1987 the scaleless male was bred to a normal female. Four fertile eggs were laid, producing three females and one male, all with normal scales and color pattern. The F1 females were sexually mature by 1989, and were bred to the original scaleless male, resulting in clutches of six, seven, and ten eggs. The 23 eggs produced four male and five female scaleless hatchlings. The scale defects of the hatchlings are essentially identical to those of the original scaleless male. The remaining 14 hatchlings had normal scales, color, and pattern.

In 1990 two F1 females were bred to a sibling, resulting in 22 eggs. All hatched, producing one male and four female scaleless phenotypes, and 17 normal hatchlings.

DISCUSSION

Though many herpetologists have never seen a scaleless snake, the few existing records suggest that a mutation for scalelessness may exist within many populations. The scaleless snakes that we have examined, and the ones described in reports, are grossly similar from the standpoint of lacking nearly all dorsal and lateral scales, but are divided into two subsets on the basis of the ventral scales: those with normal ventrals and those with ventrals divided by a longitudinal cleft. Not all may be caused by an identical mutation. Since naked snakes are conspicuous and apt to be reported when

found, the small number of records may indicate a low rate of mutation for the anomaly, low survival rate for scaleless individuals, or both.

The scaleless snakes in our possession move and feed normally. They often have difficulty with ecdysis because of the absence of scales. The thin cast has no "stretch" and the casting skin often rolls into a constricting band at the thick midsection of the snake. A normal spectacle is present.

We have had the opportunity to examine a total of 16 young scaleless *E. o. lindheimeri*, the original two from the Bronx Zoo, the nine hatched in 1989, and the five hatched in 1990. All have been much more colorful than normal, most of them suffused throughout with orange rust color. We do not believe, however, that these snakes have a color anomaly. Individual *E. o. lindheimeri* specimens vary considerably in color, largely as a result of differences in quantity and quality of red and yellow pigments in the skin that is visible between the scales. The color of the entire skin of the scaleless mutants is not obscured by a thick keratin layer and appears to be a continuation of the color that is exposed between the scales of a normal snake when the skin is stretched, as after the snake has ingested a large meal.

The results of the matings suggest in this instance that the absence of dorsal scales, with associated anomalies of scutellation, is caused by an autosomal recessive gene mutation. Homozygous recessive genotypes may then be resulting in monomorphic scaleless phenotypes. Aside from individual variation in color, all mutants are essentially identical. The mutant genes are not debilitating, and do not appear to be linked to lethal or debilitating genes. This may not be true of all mutations affecting scutellation. No snakes have been dissected to see if any visceral or skeletal defects accompany this mutation.

The scaleless mutation reported in this paper has no apparent evolutionary significance, but may be more than a curiosity. It could have potential scientific relevance.

Snakes' scales are cutaneous adaptations formed by backward overlaps of epidermis and the outermost dermis. This differentiation starts as soon as the embryo is covered by a distinct primordial epidermis and dermis. The normally unpaired ventrals arise as paired structures, fusing at the midline prior to birth or hatching (Maderson 1985). These developmental events between fertilization of the ovum and birth or hatching are better known than understood. This peculiar and startling mutation promised to provide a model for the study of the molecular and genetic basis of snake embryology.

ACKNOWLEDGMENTS

We are indebted to J. Behler and his institution for generously lending us two scaleless Texas rat snakes on a breeding loan.

USE OF ROAD-KILLED AMPHIBIANS IN ALLOZYME ELECTROPHORESIS

Each spring populations of amphibians emerge from hibernation to migrate, court, and breed. Many of these animals are killed on roads en route to the breeding ponds. Heavy road mortality has prompted conservation measures such as bypass tunnels and warning signs to motorists, but their use is relatively rare, and highway mortality continues unabated in most places. Although road-killed specimens can provide valuable distributional data, the carcasses are usually severely damaged and of little use to investigators utilizing traditional morphological techniques in systematic and population biology.

In recent years, biochemical techniques have been applied increasingly to systematics and population genetic studies of amphibians. Many spring-breeding amphibians that meet their demise on roads are killed in cool, moist conditions that are conducive to the preservation of proteins and nucleic acids. Thus, these animals could provide much genetic information; large sample sizes are often needed, particularly for the estimation of population genetic parameters. The preservation of amphibian populations is receiving increasing and much-needed attention in the literature and popular press, and efforts to reduce the number of road-killed specimens certainly should continue. In the meantime many valuable data might be garnered from specimens that would be otherwise wasted, thereby reducing collecting pressure on the remaining animals.

In an ongoing study of allozyme variation in a population of Amb*ystoma texanum* near Lawrence, Kansas, I utilized road-killed and live-caught specimens. Herein I compare the utility of both types of specimens in the analysis of enzymatic proteins.

METHODS AND MATERIALS

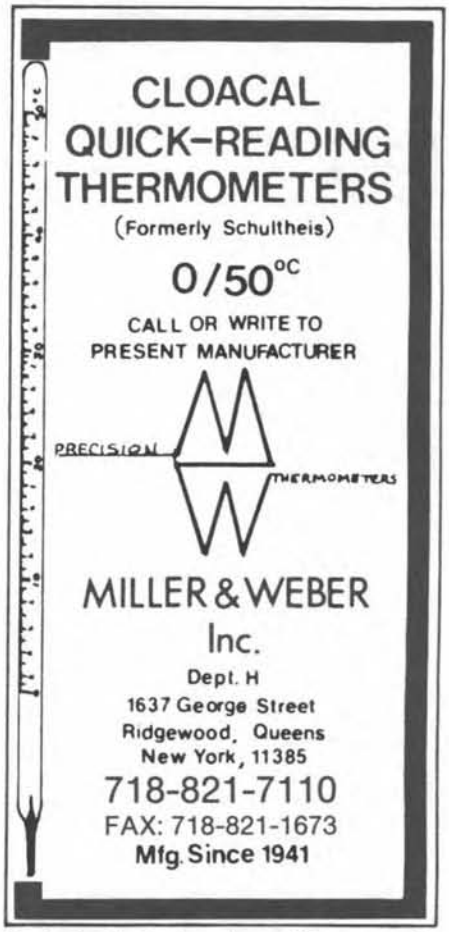
Specimens were collected March-April 1989 and January-March 1990 from roads adjoining the Baker Wetlands area of Haskell Bottoms south of Lawrence, Kansas. Conditions were wet, and temperatures ranged from 2 to 5°C. Road-killed specimens were stored at -20°C within 1 h of collection or placed on dry ice and stored at -70°C. Live-caught specimens

were stored at 4°C until used, then anesthetized with a 10% benzocaine ointment (Maximum Strength Orajel) applied topically (Altig 1980). Liver and muscle were dissected when possible, but often skeletal muscle was the only tissue available from road-killed carcasses.

Liver and muscle tissues were homogenized together (when both tissues were available) in an equal volume of 0.01 M Tris-0.001 m EDTA-0.001 M mercaptoethanol. Centrifugation was at 20,000 x g for 20 min at 4°C, and the supernatants were pipetted into clean microfuge tubes. Two buffer systems and 12% horizontal starch gels were used to resolve 14 presumptive gene loci: lithium hydroxide, 20 V/cm for 5 h (S-Aat-A, Pep-A, Pep-B, Pgm-A); and Tris-citrate, pH 8.0, 12 V/cm for 5 h (M-Acoh, Gpi-A, M-ldh-A, S-ldh-A, Ldh-A, Ldh-B, M-Mdh-A, S-Mdh-A, M-Mdhp-A, S-Mdhp-A). Enzyme nomenclature is based on the recommendations of Buth (1983) and the International Union of Biochemistry Nomenclature Committee (1984) and enzyme abbreviations follow Murphy et al. (1990). Briefly, a prefix of "S" refers to a soluble/cytoplasmic locus, whereas "M" refers to a locus expressed in the mitochondria. The next group of letters is an enzyme abbreviation and is capitalized when referring only to the enzyme and not to particular loci (e.g., LDH). The last letter describes the order in which loci of a particular enzyme were formally described, with "A" referring to the first. Staining followed standard methods (Selander et al. 1971; Harris and Hopkinson 1976). Electrophoresis was at 4°C. Homogenates from road-killed and live-caught specimens were placed on the same gel for comparative purposes. Locus homologies were determined in a previous study of tissue specificity and relative mobility (Titus, unpubl. data).

RESULTS AND DISCUSSION

In most cases no difference in overall activity of enzymes was seen for the road-killed versus live-caught specimens. Exceptions to this pattern were in cases where only skeletal muscle was available from a road-killed specimen and the enzyme in question displayed higher activity in liver than in skeletal muscle (e.g., S-lcdh-A).



Secondary isozymes are bands resulting from various posttranslational modifications to the secondary or tertiary structure of a gene product; production of these multiple bands depends on numerous nongenetic factors involving both in vivo and in vitro processes (summarized by Richardson et al. 1986; Murphy et al., 1990). Secondary isozymes migrating anodally to the major isozyme were present in both road-killed and live-caught samples in S-Aat-A, Gpi-A, M-ldh-A, S-ldh-A, Ldh-B, M-Mdh-A, S-Mdh-A, Pep-A, and Pgm-A. The presence of secondary isozymes made the scoring of polymorphisms difficult at times, especially NAD+-dependent malate deydrogenases (MDH) and peptidases (PEP). However, no differences were seen in the amount or number of secondary isozymes in the two tissue treatments.

The elapsed time between death of the specimen and ultracold storage was the only difference between tissue treatments in this study, and seems to have made no difference in the amount or number of secondary isozymes produced. Previous work indicates that both the amount and number of secondary isozymes is reduced for many loci when homogenates are prepared from fresh rather than frozen tissues and when homogenates are used immediately without freezing (Titus, unpubl. data). Exceptions to this pattern are the malate dehydrogenase loci, which seem to produce secondary isozymes regardless of the tissue treatment. Thus, one advantage of utilizing live-caught specimens is the ability to homogenize and electrphorese fresh tissue without freezing, thereby avoiding the production of secondary isozymes that could interfere with the interpretation of polymorphic loci. However, this effect is negated as soon as tissues and/or homogenates are frozen, regardless of the collecting method.

Results indicate that if road-killed specimens are collected and frozen within 2 h of death, they provide metabolic enzymes equal in quality to those from tissues frozen from live-collected animals. The maximum amount of time that carcasses can be left without freezing has not been determined for these loci, but it is expected that this time will vary with the conditions under which the animals die, particularly temperature, as well as the species and loci that must be scored (Richardson et al. 1986). As with tissues from live-collected specimens, the investigator(s) should make every effort to minimize the time between death of the specimen and freezing of tissues. Driving roads during a breeding migration with a container of liquid nitrogen or dry ice is particularly effective in this regard.

Perhaps the major disadvantage of using road-killed animals in isozyme studies is the limited number of tissues available from some specimens. Often the viscera are missing or destroyed, and the only available tissue is skeletal muscle. Many amphibian isozymes exhibit tissue-specific expression and cannot be scored from skeletal muscle (e.g., S-Acoh-A [kidney and liver], Adh-A [liver], Iddh-A [liver, kidney, and gut], and M-Sod-A [heart]). These problems can be minimized by choosing loci that exhibit high activity in a variety of tissues (e.g., M-Acoh-A, Gpi-A, Pep-A, Tpi-A,and Mpi-A) or are strongly expressed in skeletal muscle (e.g. Ck-A), which is nearly always available.

Road-killed amphibians can be a valuable source of biochemical data and should be considered by biochemical geneticists as an alternative to live-caught specimens. Use of these specimens in biochemical analyses is not without problems, particularly with regard to the limited number of tissue types sometimes available. However, the needs of a study can often be met or supplemented without adding collecting pressure to a population already reduced by automobile traffic.

MATING AND COMBAT IN *Varanus indicus*

The mangrove monitor has a range encompassing extreme northern Australia, New Guinea, and the Caroline, Marshall, and Mariana Islands (McCoy 1980). Introduced populations are known from the western Carolines (Uchida 1966). *Varanus indicus* is the only species of monitor in the Marianas and occurs on most islands except the northernmost three (Asuncion, Maug, and Fallaron de Pajaros) (G. Rodda, pers. comm.).

The best studied populations occur on Guam, the southernmost island in the Mariana chain. Dryden (1965) reported on food habits and feeding behavior and Wikramanayake and Dryden (1988) described reproductive ecology. Because of the reproductive cycle observed by Wikramanayake and Dryden and the size disparity between the sexes (males are larger than females), these authors predicted that copulation should occur in the latter part of the wet season to early dry season and that it may involve male-male combat and forced inseminations of females.

We herein report on observations of copulation and combat in *V. indicus* on Guam. Most observations were made viewing from inside a house in the village of Malojloj, Inarajan Municipality. Terminology is based on Auffenberg (1988). Monitors were abundant and could be observed virtually daily, sunning or actively foraging, at or adjacent to the study site.

Monitors were unmarked and sex was assumed from behavior described below.

Episode 1. On 15 April 1990 at 1405 h, a [ca. 1 m total length (TL) female] monitor was observed sunning on the top of an exposed rock face immediately adjacent to the house. At 1406 h, a second (ca. 1 m TL male) monitor appeared at the base of the rock face and slowly climbed up tongue-flicking and head-probing the surface of the rock. When the second monitor encountered the first, he immediately mounted the female and exhibited chin-rubbing on the dorsum of the female's head and forequarters. They were oriented head-to-head and slowly rotated in a clock-wise direction through 360° over a 18 min period with the male remaining superior. Two copulations were noted during this period, each lasting about 30 sec. During each intromission, the male rhythmically pumped 10 to 15 times. Intromission was immediately preceded by the male scratching the female with his right hind foot on the base of her tail. The female would then raise her tail and cloacal apposition resulted with the male using the right hemipene.

At 1424 h, a third monitor (ca. 1.2 m TL male) appeared at the base of the rock face and moved slowly up towards the copulators. The first male climbed off the female and faced the second male. Both displayed lateral compression and gular extension. The first male lunged at the second, larger male and ended up lateral to him in a parallel, head-to-tail position. Both simultaneously bit the base of the tail of the other, rolled down the rock face into the vegetation and out of view. The female remained quiescent during this combat and at 1426 h moved out of view behind the rock.

At 1430 h, the second male monitor (presumably the victor) reappeared at the base of the rock face and climbed slowly up the rock face and out of view (1435 h) behind the rock. At 1440 h both the female and and the second male moved up the far side of the rock and reappeared at the crest. Observations were somewhat obscured by vegetation but by 1452 h, at least two copulations had occurred.

The second (larger) male spent less time mounted on the female than the first (smaller) male. Most of the time, the second male was side-by-side to the female. During copulations, the second male used his hind feet to anchor himself and the female to the rock surface. Observations were terminated at 1452 h.

Episode 2. On 4 July 1990, 1655 h, a male (ca. 1.3 m TL) monitor was observed mounted on a female (ca. 0.9 m TL). Both were quiescent. On 5 July 1990, 0620 h, the presumed same two individuals were seen, still mounted, on the rock crest where they may have spent the night. At 1530 h, after a nine hour hiatus, observations were resumed and both monitors were on the rock face. Both remained quiescent until 1620 h when the female moved slightly and the male responded by chin-rubbing her head and forequarters. This sequence was repeated at 1645 h and 1647 h. At 1648 h the male exhibited a series of 10 to 15 pelvic thrusts lasting ca. one min, but there was no cloacal apposition. At 1653 h, the female attempted to move from beneath the male. The male maintained a straddling position and both moved clockwise through 360° over a six min period. At that time, the male scratched the base of her tail with his right hind leg and the female raised her tail, exposing her vent. Cloacal apposition

immediately followed. At 1704 h, the male disengaged, remained straddling the female, and both were quiescent until 1720 h. At that time, and at 1730 h and 1743 h, she moved slightly, each time eliciting chin-rubbing by the male on her head and forequarters. At 1744 h, the female rapidly moved from beneath the male, voided 2-3 cc of white fluid from her vent, and disappeared over the rock crest. The male rapidly followed.

The copulatory events seen on 15 April 1990 and 5 July 1990 occurred at the height of the dry season and at the beginning of the wet season, respectively. Additionally, a copulation was observed on 27 January 1989 (different site), at the beginning of the dry season. Wikramanayake and Dryden (1988) predicted reproductively associated copulation from September through January (late wet season to early dry season) which is contrary to our observations of copulatory behavior over the entire dry season and into the wet season (January through July). Our observations of mating correspond with the period of highest female Gonadosomatic Index (January to May) (Wikramanayake and Dryden 1988).

The predictions of male-male combat and forced inseminations by Wikramanayake and Dryden are supported by our observations. The second (larger) male in Episode 1 and the male in Episode 2 both maintained apparent physical and behavioral control of the females. Since the first male in Episode 1 was approximately the same size as the female and did not anchor himself or the female during copulations, size may be a factor in forced inseminations. In addition, size of males may play a role in combat as the larger of the two males in Episode 1 was the victor. During periods of the year with no mating behavior (February through December), size is important in dominance interactions. For example, control of basking sites is related to size as the largest individuals bask in the morning and are replaced by sequentially smaller individuals through the day.

TECHNIQUES

A TECHNIQUE FOR THE SAFE RESTRAINT OF VENOMOUS SNAKES

The various methods of immobilizing venomous snakes all have their associated advantages and limitations. The use of clear cast acrylic tubing (Murphy 1971) has become common over the years because of its safety and the reduced stress to the snake. A survey by the SSAR Zoo Liaison Committee (Zantzinger 1986) showed that 21 of the 30 submitting institutions routinely utilize acrylic tubing to restrain venomous snakes.

A problem often associated with this type of restraint is the coercing of the snake into the tube. Murphy (1971) recommended placing the snake on a smooth surface, directing the tube over the snake's head, then lightly tapping the posterior section of the snake's body. Almandarz (Fowler 1978a) and Fowler (1978b) suggested locating the tube along the intersection of a wall and floor to direct the snake into the tube. Both of these techniques are effective but offer limited control over the snake and can prove to be time consuming.

In 1982, at the Oklahoma City Zoo, we developed an alternative method of coercing a venomous snake into a tube that increases control, is time efficient, and eliminates many other variables that can interfere with this restraint process. This technique has been used successfully on numerous viperids, elapids (*Aspidelaps*, *Micrurus*, and *Naja* less than 1.5 m in length), and opisthoglyphs (*Boiga* and *Oxybelis*).

A sanitized plastic trash barrel is selected of a size that allows the snake to move freely about the bottom but does not enable it to climb upward over the rim. The barrel is filled with water (ambient temperature) to a depth that prevents the snake from securing itself on the bottom. A depth of ca. 12 cm is appropriate for many viperids. After the snake is placed in the barrel, an appropriate size tube (Murphy 1971, Fowler 1978) is placed over the snake's head, gently submerging

Figure 1. Placing the tube over the head of the snake causes the snake to move up the tube.

Figure 2. After the snake has moved a safe distance up the tube, immobilize the snake by simultaneously grasping its body and the tube.

it (Fig. 1). The acrylic tube should be a diameter that prevents the snake from turning backwards inside the tube, and the tube end opposite the snake can be closed with a plug for additional safety. Finding this submerged position undesirable, the snake searches upward into the tube, securing itself on this firm surface. When the snake has reached a safe position midway up the tube, its midbody should be firmly and gently pressed against the barrel bottom to prevent further movement. The snake's body and tube end should be grasped firmly with one hand (Fig. 2). The tubed snake then can be removed from the barrel for the desired procedure.

The snake is released from the tube by simply letting it move out of the tube into its enclosure while the tube is held with tongs.

This technique has been utilized at the Oklahoma City Zoo and Louisville Zoological Garden for the last eight years without incident. We believe that it increases handler safety, decreases trauma to the snake, and saves time that otherwise would be spent in coercing the snake to move into the tube.

A METHOD OF SEXING THE DUMERIL'S MONITOR, *Varanus dumerili*

Many varanids lack sexually dimorphic external characteristics other than differences in size (length and mass) (Wikramanayake and Dryden 1988). This paper reports attempts to find a reliable, non-invasive technique for sexing *Varanus dumerili* at the National Zoological Park, Washington, DC. Previously, sex determination in this species was based on agonistic or submissive behaviors (Horn 1985; Davis et al. 1986) or hemipenial eversion in males. Snake sexing probes were used as described by Frye (1981), but the results were not consistent with observations of copulation and egg laying.

Initially, the pelvic area and anterior aspect of the tail were radiographed in an attempt to demonstrate keratinized or calcified hemipenial spicules or more pronounced ossifications similar to those seen in *V. komodoensis* by Shea and Reddacliff (1986). Four adult *V. dumerili* (1820-1980 g mass; 46.9-47.8 cm SVL) were radiographed on detail radiography casettes. However, no discernable evidence of hemipenial structures was revealed.

Fiberoptic laparoscopy was then used to make conclusive sex determinations. Each monitor was tracheally intubated and placed on inhalation anesthesia utilizing isoflurane (Aerrane®, Anaquest, Madison, WI) delivered in oxygen with a non-rebreathing T-piece apparatus. The animals were maintained at a surgical plane of anesthesia to achieve adequate relaxation for the procedure. Anesthesia also protected the lizards from possible trauma that might be incurred from the instruments while struggling under manual restraint, and it also protected the delicate instrumentation from damage.

A Wolf® (Richard Wolf Medical Instruments, Rosemont; IL) 2.7 mm arthroscope and its associated cannula were introduced at the cloacal opening and directed caudally at the lateral aspects, on each side of the cloaca, to enter the inverted hemipenes in a male or the cloacal evagination in a female. Observation of these structures was achieved by inflating them with air using a hand-bulb apparatus attached to the arthroscope cannula. Insufflation creates a visual space for viewing the structures in both sexes. Marked differences between them were demonstrated.

In the two males, insertion and inflation permitted cannulation of inverted hemipenes to a depth of 3.5-4.0 cm, and observation of the folded, expansive mucosa and any small mucosal structures on the walls of the inverted hemipenes. A constriction was encountered at a depth of 1.5 cm, but because of the anesthesia it was possible to pass the narrowing with the arthroscope and visualize the expanded cavity beyond.

In the two females, the pouches rapidly tapered caudally, only permitting insertion of the 2.7 mm-diameter arthroscope

to a depth of 1.5-2.0 cm. In all cases a narrow extension of each cloacal evagination, ca. 1.0-1.5 cm in depth, could be seen beyond this point.

Minton and Minton (1973) described the cloacal evagination in a group of dissected female *V. bengalensis*. They noted that the evaginations resembled those of males, but were about half the size. In *V. dumerili*, the distance corresponded to the arthroscopic penetration depth of the cloacal evagination in females. A 2 mm snake sexing probe would tend to stop at the hemipenial constriction in males, especially without anesthesia or inflation, and a male could easily be mistaken for a female.

Fiberoptic laparoscopy, allowing visualization of the cloacal evagination, can be used to make accurate sex determinations in adult *V. dumerili*. This technique may also be applicable to other varanids, as well as to other families of lizards where sex determination is difficult. It offers an alternative to coelomic laparoscopy, which visualizes the gonads.

ACKNOWLEDGMENTS

A NEW METHOD OF TRAPPING GOPHER TORTOISES (*Gopherus polyphemus*)

Two methods are normally used for capturing gopher tortoises (*Gopherus polyphemus*), other than picking them up when away from their burrows: 1) the use of a pitfall or bucket trap buried at the burrow entrance and 2) the use of a long, stiff piece of wire to hook and pull tortoises from their burrows. Both methods have drawbacks. Pitfall traps can be laborious to install. If not checked frequently, they can subject tortoises to heat stress from exposure to direct sunlight, and can cause drowning if the traps fill with water (E. Wester, pers. comm.). Also, installation of the bucket may damage tortoise eggs, which are often laid at the burrow entrance. Pullers can injure or kill tortoises due to damage by the wire; furthermore, they require experience and skill to be used successfully.

During the summer of 1988, we designed and tested a new trapping method for capturing gopher tortoises. The materials for building a trap are: one 1" x 2" x 8' board (the "arm"), two 1" x 2" x 8" boards (the "pivot supports"), one 2" x 2" x 4' board (the "upright"), three 5/16" x 3 1/2" standard bolts and nuts, six 5/16" standard flat washers, one net (see below for type), three eyescrews (#6 or #8), one spring (Century C355 or equivalent), nylon seine twine (#18, about 28 feet), and one trigger (see below).

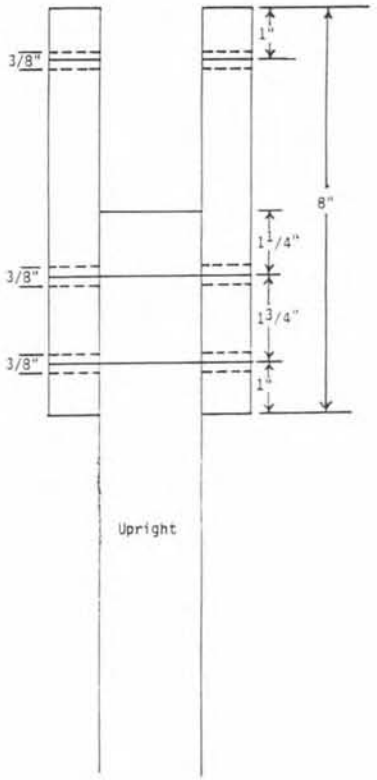

Figure 2. Top of "upright" of gopher tortoise trap showing placement of holes.

The basic design of the trap involves a spring-loaded arm which, when released by a trigger mechanism activated by the tortoise, raises a net to form a purse around the subject; the arm pivots on an upright that has been driven into the ground beside an active burrow (Fig. 1). One end of the upright is cut at a sharp angle to facilitate driving into the ground. The pivot is formed by attaching two 1" x 2" x 8" boards (the "pivot supports") to the top

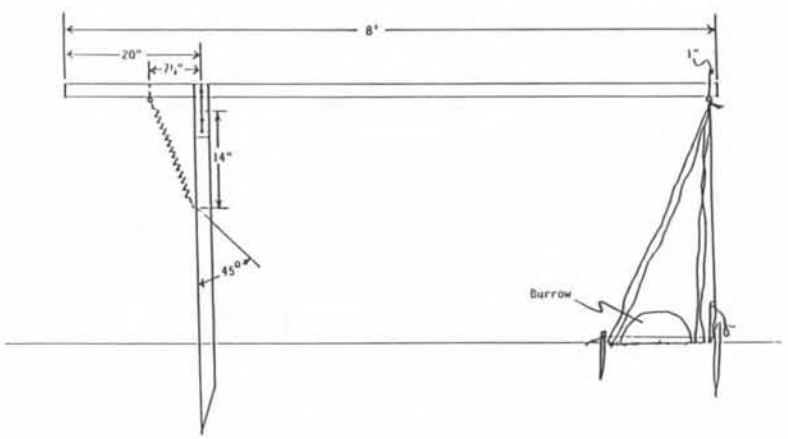

Figure 1. Gopher tortoise trap.

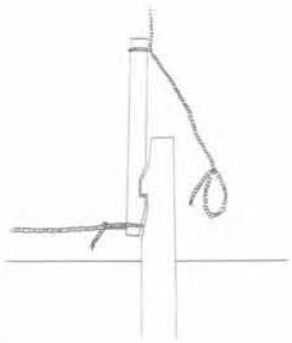

Figure 3. Trigger mechanism for gopher tortoise trap

end of the upright (Fig. 2). The supports are attached by drilling two 3/8" holes 1 3/4" in each pivot support, with the first hole being made 1" from the end of the support. A third 3/8" hole is drilled 1" from the opposite end of each pivot support. Two 3/8" holes are drilled in the upright at 1 1/4" and 3" from the top. Bolts are then used to attach the pivot supports to the upright so that each support extends 4" beyond the upright.

Attachment of the arm (1" x 2" x 8') requires drilling a 3/8" hole 20" from one end. The arm is placed between the pivot supports and a bolt serves as a hinge.

To install the spring, a small hole is drilled into the bottom of the short end of the arm 7 1/2" from the hinge. Another hole is drilled into the side of the upright 14" from its top and facing the previous hole (at a 45° angle). An eyescrew is then screwed into each hole until flush, and the spring is hooked between the eyescrews. A final hole is drilled 1" from the end of the arm opposite the spring, and an eyescrew is installed. The trigger and net attach to this "trigger eyescrew."

Many types of net can be used for the trap. Of all nets tried, a piece of volleyball net (4" nylon mesh) proved to be most reliable. We found 1/4" woven seine nets to be unsatisfactory. The tortoises had a tendency to destroy the net and escape. However, the volleyball net had a tendency to untie, and small juveniles passed through its large mesh. Another possibility may be a tennis net, though this is untried.

The net is cut into a square, 36" on a side. Four strings (63" long) are attached to the net, one to each corner. A small loop (0.5" diameter) is tied at one end of each string. Beginning at one corner, a string is woven along one margin of the net and the loop is tied securely to the adjacent corner (we found this helpful to prevent the loop from "backsliding" through the weave). The next string is passed through this secured loop, woven, and attached as the previous string. The final two strings are placed similarly. The free ends of the strings are tied together and attached to the trigger eyescrew. The result is a net that will close at the top when the strings are pulled.

To construct a trigger, two relatively straight pieces of wood (we used tree branches) are cut, one ca. 5" long and 0.5" in diameter and the other ca. 12" long and 1" in diameter. Both are notched as in Fig. 3. The short piece of wood (the "upper trigger") is attached to a length of string 36" long, and the opposite end tied to the trigger eyescrew. Excess string should be left dangling from the upper trigger to allow a loop to be tied (Fig. 3). This will help facilitate setting the trap. The unnotched end of the long piece of wood (the "lower trigger") is whittled to a point to allow it to be driven into the ground. An additional 4' string serves as the "trip string."

Setting the trap involves five steps.

1) The trap is first "gauged" for proper placement beside the burrow using the following method: The spring is disconnected to allow the arm to swing freely. The upright is set to one side of the burrow entrance so that when the arm is flexed, the net spreads across the apron of the burrow and the trigger eyescrew is directly above the far edge of the net. This will assure that the tortoise cannot avoid contact with the net and trip string.

2) Once properly gauged, the top two bolts of the pivot support are removed and the bottom bolt loosened to allow the two pivot supports to swing out of the way. The upright is then driven into the ground until sturdy. The pivot supports and the arm are rebolted to the upright and the spring reconnected.

3) Next, the lower trigger is driven into the ground directly below the upper trigger. Once driven in, the trigger should be tested for a proper fit as in Fig. 3. At this point, the height of the closed net is adjusted so that the bottom of the net is about 3" off the ground when the arm is fully extended. This will assure that the net closes properly around the tortoise. The tension on the net should also be such that the netted tortoise can crawl partially into its burrow to avoid heat and predators. This is tested by pulling down on the net strings with the trap arm extended. The maximum tension should not exceed 2 lbs. Adjustments for too much or too little tension can be made by relocating the spring eyescrews on the upright and the arm.

4) The arm is swung down and the loop of the upper trigger placed on the lower trigger to act as a safety. The net is spread over the burrow apron, with one corner of the net inserted into the burrow entrance. Sand is spread over the net, particularly in the entrance, to prevent the tortoise from crawling under the net.

5) Finally, a non-slip loop is placed at one end of the trip string, and the other end is wrapped around an anchor stick. The anchor is pushed into the ground on the opposite side of the net from the trigger. This prevents the tortoise from missing the string when exiting its burrow. The trip string is stretched over the net and the trigger is set, this time with the loop in the trigger (Fig. 3). The safety loop is placed out of the way beside the trigger or temporarily tied to the upper trigger.

A snare trap can be set in 10 to 15 minutes with practice. Advantages of this type of trap are: minimization of overheating and drowning (none of the tortoises captured by this method in 1988 or 1989 appeared heat stressed), reduction of disturbance to eggs and/or hatchlings, and elimination of possible changes in the drainage pattern of the burrow (all potential problems with pitfall traps). Disadvantages include slight damage to the top of the burrow entrance, caused by rubbing of the strings attached to the net on the burrow entrance. Occasionally, abrasions by the net appear on the gopher tortoise's legs. However, we have never observed these abrasions to result in bleeding. Since this device is highly visible, it may be subject to theft or vandalism in some areas. We suggest checking traps every 3-4 hrs. and more often during extremely hot weather, since a net may snag a low-hanging limb or a root and prevent the tortoise from entering its burrow.

Thirty-one tortoises were caught during the summer of 1988. Three were recaptured the same year with the same trap while one was captured three times using this method. Of 47 tortoises captured in 1989, 18 were recaptured once and three were recaptured twice that year. Seventeen of the tortoises captured in 1989 were previously captured in 1988. The tortoises do not appear to become trap wary with this new design.

THE USE OF BACTINE® IN THE TREATMENT OF OPEN WOUNDS AND OTHER LESIONS IN CAPTIVE ANURANS

The long-term maintenance of amphibians (frogs and toads of the genera *Rana*, *Bufo* and *Hyla*) for research has been an on-going problem in our lab because animals acquire abrasions, sores and open wounds, infection from periodic sampling by maxillary-vein puncture, and injuries from banging their snouts against the holding containers while in captivity. Open sores that become infected may be fatal.

Bactine® (Miles Laboratories Ltd.), a topical antiseptic available in liquid atomizer or canned aerosol for human use, was found to be of great value when applied liberally to open wounds on anurans. The active ingredients, 0.14% w/w benzalkonium chloride and 2.6% w/w lidocaine hydrochloride in a non-alcohol base, are non-irritating to frogs and toads and appears to promote rapid healing. Bactine® is applied to the lesion once daily until a layer of white scar tissue covers the wound. Treated animals are housed separately.

We were first inspired to the potential effectiveness of this product by a report in which a cat suffering from massive electrical burns was successfully treated using this substance (Breathed 1986).

Bactine® appears to be effective for deep facial wounds, in which the maxillae, nasal and fronto-parietal bones become exposed, as well as wounds to the extremities, such as torn skin or lost digits. We observed that scar tissue formation began as early as one day post-treatment with the antiseptic, and cases of severe oedema were alleviated as rapidly, with no apparent adverse effects to the animals. Without Bactine®, wounds healed much more slowly, taking weeks or months, often becoming severely infected. This product has also been useful in cleansing the skin of anurans for aseptic venipuncture and may be useful in preparation for surgery without the use of stringent antiseptics (such as isopropyl alcohol) which are injurious to the thin, sensitive skin of frogs and toads. Although a controlled experiment is not presented in this report, three years of casual observation on the survival of field-collected anurans suffering from the aforementioned injuries before the therapeutic use of Bactine® was initiated, clearly shows a marked improvement in recovery rate with treatment. Other workers may wish to conduct controlled studies with the product to verify our observations.

With amphibian populations dwindling (Barinaga 1990), these animals are becoming increasingly difficult to find in the field. The novel application of this antiseptic for use on animals held in captivity may help to reduce the number of fatalities due to infection, and increase the number of anurans returned to the field after they have been studied.

ACKNOWLEDGMENTS

We are grateful for the support of Dr. Sherwin Desser and funding from NSERC (PGS I Scholarship to DM). We also thank Mark Siddall and Lisa Waldhauser for their comments on this manuscript.

Animals are maintained in accordance with the guidelines of the Canadian Council on Animal Care (1980-1984).

A SIMPLIFIED FLUORESCENT MARKING TECHNIQUE FOR IDENTIFICATION OF TERRESTRIAL SALAMANDERS

Fluorescent pigments (available from Scientific Marking Materials, Inc., Box 24122, Seattle, Washington, 98124 and Radiant Color Co., 2800 Radiant Ave., Richmond, California 94804) were first used to mark vertebrates by Phinney et al. (1967), and have been used to mark salamanders by Ireland (1973, 1989), Taylor and Deegan (1982), and Nishikawa and Service (1988). Ireland (1973) applied fluorescent pigment paste with a hot probe. Taylor and Deegan (1982), Nishikawa and Service (1988) and Ireland (1989) applied pigments with gas pressure. These methods tagged terrestrial salamanders for up to one year and larval salamanders for shorter periods of time. These methods require either a heat source or compressed gas and a spray gun to induce superficial skin lesions and apply pigments. The pigments become incorporated into the disrupted skin and result in an identifiable tag when illuminated with UV light. Equipment necessary for pigment application may be cumbersome to use in some field situations. I have developed a simplified technique for application of fluorescent pigments to terrestrial salamanders in the field.

This method requires pigments, glycerol, blunt probe and a typewriter print eraser in the form of a pencil. The eraser point should be flattened to produce a disk equal to the size of the tag desired. I have found 1-2 mm diameter marks to be most efficient for *Eurycea longicauda* and 2-3 mm diameter marks most efficient for *Ambystoma maculatum*. I place the shaped end of the eraser on the surface I wish to mark and spin it two to three times with light downward pressure. The pressure should be enough to allow the abrasives imbedded in the rubber matrix of the eraser to slightly roughen the skin surface without damaging deeper skin tissues. I then dip the blunt probe in glycerol and then in the pigment which adheres to the glycerol and gently press on the skin surface disrupted by the eraser. By combining the 12 colors of pigment currently available to different parts of the body a large number of salamanders may be individually marked.

I have found this method will result in tags that can be readily distinguished on terrestrial salamanders for one season

(spring through fall) but is not reliable for longer periods of time. This method does not work well on aquatic larvae, possibly due the the rapid growth and subsequent loss of skin during this life stage. This technique does not appear to adversely affect salamanders. Although this method does not produce a long term tag, as does acrylic polymer injections (Woolley 1973; Cecil and Just 1978), it is simple, rapid and suitable for studies that require short term recognition of individuals.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19: 1–41), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author — curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 3: 802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full — spell out state names — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. All specimen identifications *must* be verified by another authority (not one of the authors). Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to: Joseph T. Collins or Darrel Frost, Section Coeditors, Museum of Natural History — Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454 USA. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic Distribution: *Lampropeltis triangulum multistriata*. SSAR Herp. Review 25: 198.

Wasco Co: Near rimrock on S side of Eightmile Creek canyon, 6.0 km northwesterly via National Forest Secondary Route 4460 & Forest Route 4460/017 from National Forest Primary Route 44 (Dufur Mill Road), S 1/2 Sec. 2, T2S, R11E. 26 May 1990. J. Kirk. Verified by Joseph J. Beatty and Robert M. Storm. OS 90004. R. Forbes discovered the Ramsey Creek site on 7 October 1982. J. Kirk discovered the other sites and collected the voucher specimens on the dates indicated.

Voucher specimens also have been deposited in the Portland State University Collection of Vertebrates (PSU 3276-3279). These are the first records of any plethodontid from east of the crest of the Cascade Mountains in Oregon (other than in the Columbia River Gorge), and also are the first records of any plethodontid from Wasco County (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest, Univ. Press Idaho, 322 p.).

DESMOGNATHUS FUSCUS FUSCUS (Northern Dusky Salamander). CANADA: PROVINCE OF QUEBEC: MRC DE L'ERABLE, Canton de Chester, 1.9 km S and 3.8 km W of Trottier, Ruisseau Gobeil, 46° 02' N, 71° 44' W, 27 May 1985, 1000-1030hr, 1 specimen (spec) found, NMC 27404(1). MRC DE LOTBINIÈRE, 3.4 km S and 4.5 km E of Saint-Sylvestre, Rivière Filkars, 46° 19' N, 71° 10' W, 27 May 1985, 1355-1420hr, 1 spec, NMC 27409(1). MRC DES ETCHEMINS, Canton de Ware, 3.6 km S and 3.0 km E of Saint-Luc, unnamed tributary of Petite Rivière Etchemin, 46° 28' N, 70° 26' W, 28 May 1985, 1250-1320hr, 4 spec, NMC 27422(4). All specimens collected by W.F. Weller & J.E. Cebek. Verified by F.R. Cook, National Museums of Natural Sciences (NMC).
The above records extend range 170 km to the NE (Weller 1977. Can. Field-Nat. 91(3): 299–303), and 90 km to the N (Denman 1981. Herp Review 12(3): 82–83), and significantly fill the gap between records to the south reported in Weller (1977) and Denman (1981), to the east (DeGraaf and Rudis 1983. Univ of Massachusetts Press, Amherst, Mass), and to the S of two records from near the base of the Gaspé Peninsula (Cook 1984. National Museum of Natural Sciences, National Museums of Canada. 200pp). Number of specimens observed is indicated after the locality. Specimens were deposited in the preserved collection at the National Museum of Natural Sciences (NMC), Ottawa. Number after museum acronym refers to catalogue number, and, in parentheses, number of specimens retained. Notes and coloured photographs of habitats ar filed at NMC.

COMPTÉ DE L'ISLET, Municipalité de Sainte-Aubert, 2.3km S and 4.9 km W of Pellerin, Décharge du Lac Chouinard, 47° 08' N, 70° 09' W, 29 May 1985, 1550-1605hr, 1 spec. COMPTÉ DE L'ISLET, Minicipalité de Sainte-Aubert, 0.6 km S and 6.4 km W of Pellerin, Rivière Trois Saumons, 47° 09' N, 70° 10' W, 29 May 1985, 1525-1540hr, 6 spec, NMC 27435(5). COMPTÉ DE KAMOURASKA, Municipalité de Mont-Carmel, 2.9 km N and 2.8 km W of Bretagne, Rivière de la Boutelillerie, 47° 23' N, 69° 45' W, 29 May 1985, 1405-1430hr, 1 spec, COMTÉ DE KAMOURASKA, Municipalité de Mont-Carmel 3.6 km S and 3.4 km E of Eatonville, Décharge du Lac du Loup, 47° 18' N, 69° 38' W, 29 May 1985, 1325-1340hr, 4 spec, NMC 27434(4). COMPTÉ DE KAMOURASKA, Municipalité de Saint-Athanase, 2.2 km S and 2.1 km E of Picard, unnamed stream,

47° 29' N, 69° 28' W, 29 May 1985, 1135-1200hr, 9 spec, NMC 27433(5). COMPTÉ DE KAMOURASKA, Municipalité de ville de Pohénegamook, 0.2 km S and 0.6 km E of Pelletier, unnamed stream, 47° 32' N, 69° 24' W, 29 May 1985 1015-1030hr, 1 spec, NMC 27431(1). COMPTÉ DE KAMOURASKA, Municipalité de ville de Pohénegamook, 2.0 km N and 2.9 km W of St-Eleuthère, Rivière Boucanée, 47° 30' N, 69° 19' W, 29 May 1985, 1055-1110hr, 2 spec, NMC 27432(2). All specimens collected by W.F. Weller and J.E. Cebek. Specimens sent to NMC verified by F.R. Cook, and to ROM by R.D. MacCulloch.

These records close the gap between those to the southwest (Weller 1977. Can. Field-Nat. 91(3): 299-303), to the northeast (Denman and Denman 1985. Herp Review 16(3): 83; and Denman, Schueler, and Weller 1990. Herp Review 21(2): 36-37), and to the east (DeGraaf and Rudis 1983. Univ of Massachusetts Press, Amherst, Mass). Number of specimens observed is indicated after the locality. Some specimens wrre deposited in the preserved collection at the National Museum of Natural Sciences (NMC), Ottawa, and others in the frozen tissue collection at the Royal Ontario Museum (Rom), Toronto. Number after museum acronym refers to catalogue number, and in parentheses, number of specimens retained. Notes and coloured photographs of habitats are filed at NMC.

TESTUDINES

GRAPTEMYS CAGLEI (Cagle's Map Turtle). USA: TEXAS: COMAL Co: 10 km SW of Fisher at Cypress Cove, 21 June 1989. West Texas State University Museum of Natural History (WT 12535), and Guadalupe River, 3 km SSE of Sattler on River Road, 26 July 1989, WT 12539. GUADALUPE Co: 5 km E of Schumansville at the upper end of Lake McQueeny, 20 March 1990, WT 12799. VICTORIA Co: Guadalupe River, 5 km SW of Nursery on FM 447, 28 May 1989, WT 12570, and Guadalupe River at Riverside Park in Victoria, 14 March 1989, WT 12126. KERR Co: Guadalupe River, 3 km SW Comfort on Hwy 27, 25 July 1990, WT 12886. GONZALES Co: 6 m SW of Gonzales on FM 2091 at Wood Lake, 18 March 1989, WT 12512, and 5 km ESE of Belmont on Alternate Hwy 90 at Lake Gonzales, 13 March 1989, WT 12576. All Specimens collected by Dan Porter and Flavius C. Killebrew. All specimens verified by Derl Brooks, Department of Biology and Geosciences, West Texas State University.

All are new county records except the specimens from Kerr and Gonzales Counties. The Kerr County specimen extends the original record 53 km ESE, and the Gonzales County specimen extends the previous record 20 km W (Haynes and McKown 1974, Tulane Stud. Zool. Bot. 18(4): 149). The new county records are from small disjunct populations in their respective counties. Funding for these surveys was from the Texas Coordinating Board's Advanced Research Program (Grant 1157) and a Killgore Research Grant.

Submitted by **FLAVIUS C. KILLEBREW** and **DAN A. PORTER**, Department of Biology and Geosciences, West Texas State University, Canyon, TX 79016, USA ●

GRAPTEMYS KOHNII (Mississippi map Turtle). USA: MISSISSIPPI: RANKIN Co:

Pearl River at Jackson, ca. 2.5 km north of US Rt. 25 bridge (Sec. 20, T6N, R2E). 5 September 1989. R. L. Jones and T. C. Majure. Verified by T. L. Vandeventer. Mississippi Museum of Natural Science (MMNS 2718, adult male). Same locality. 15 October 1990. R. L. Jones and K. R. Macaro. Verified by T. L. Vandeventer. MMNS 2719, adult male. First records from Pearl River (Lohoefener & Altig 1983, Mississippi Herpetology. Mississippi State Univ. Research Center Bull. No. 1, 66 pp.). Given the proximity to residential areas of Jackson, these specimens are believed to be either released captives or the progeny of released captives.

Submitted by **R. L. JONES** and **TERRENCE C. MAJURE**, Mississippi Department of Wildlife, Fisheries, and Parks, Museum of Natural Science, 111 N. Jefferson Street, Jackson, Mississippi 39201 and **KENNETH R. MACARO**, 124 Longmeadow Road, Brandon, MS 39042, USA ●

HYDROMEDUSA TECTIFERA (Tortuga de Rio). ARGENTINA: MISIONES: Oberá Department: Arroyo Chico, environs of Oberá City. February 1961. J. M. Cei, V. G. Roig and Benitez. Verified by R. F. Laurent. Herpetological collection, Instituto de Biología Animal, Universidad Nacional de Cuyo (IBA - UNC Chel, 0210). First record for the Department. The species was previously recorded from Misiones Department of Iguazú, General Manuel Belgrano (Waller & Chébez 1987. Hist. Nat. 7 (5): 53-59) and Leandro N., Alem (Richard & Morgenstern, 1990. SSAR Herp. Review, 21 (2): 39).

Submitted by **ENRIQUE RICHARD**, Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 - Tucumán, República Argentina and Proyecto Tortugas (FVSA), Sección NOA, Rivadavia 105 - 5to "G," 4000 - Tucumán, República Argentina ●

PHRYNOPS HILARII (Tortuga de Laguna). ARGENTINA: CORRIENTES: Goya Department: Santa Lucía river, environs of Goya City. 10 June 1988. Armando Morgenstern. Verified by Raymond F. Laurent. Herpetological Collection, Fundación Miguel Lillo (FML, Chelonii 028, Adult). First definite record with precise locality data known for the province. This species was previously cited for many years (since 1872) in the Corrientes sector of Paraná River (Gray, 1872. Ann. Mag. Nat. Hist. London (4) 10: 463 and Freiberg, 1939. Mem. Mus. Entre Ríos, Zool., 11:3-28), but this river is ca. 650 km long in the province.

PODOCNEMIS ERYTHROCEPHALUS (Tracaja Piranga). BRASIL: PARA: 3 km upstream from Alter do Chao, Rio Tapajos, Laguna Jurucui; 23 April 1989. Richard C. Vogt & Augusto Fachin. Verified by C. J. McCoy. Adult female 23.5 cm carapace length. Specimen photographed (CMNH 34572), marked, and released; Alter do Chao Laguna Verde, Igaripe' II. 25 November 1989. Pierre Armond, Olga Victoria Castano, Tibisay Escalona, Thierry R. J. Gasnier, Hedelvy Gvada, Barbara Mann, Isnaldo Luiz Melo Da Silveira, Cesar Augusto Monje Carrillo, Ronis Da Silveira, Aydil de Souza Marques, Jose Carlos Paula Raposo, Franklin Rojas Sulrez, Waldemar da Rocha Amazonas Filho, and Richard C. Vogt. Verified by William Magnusson. Adult female 25.5 cm carapace length, with 9 oviducal eggs. Whole blood, heart, liver, and striated muscle frozen in liquid nitrogen. Instituto Nacional Pesquisas Amazonas (INPA 330). The validity of the Santarem records (Naturmuseum and Forschungsinstitut Senckenberg, Frankfurt; SMF 57952-3, collected by de Rover 1960) has been questioned by Mittermeier and Wilson (1974. Papeis Aulsos de Zoologia, Sao Paulo. Vol. 28(8):147–162) and Iverson (1986. A checklist with distribution maps of the turtles of the World. Paust Printing, 282 pp.). They thought that this species primarily occurred in black water rivers and suggested that the specimens from Santarem on the Tapajos River, a clear water river, might have been "stragglers from black water rivers." Also Mittermeier and Wilson mentioned they were unable to find them in the Santarem area and that the local inhabitants were unfamiliar with this species, however they cited six other vernacular names for the species not the one that is used by the locals in the Santarem-Alter do Chao area, Tracaja Piranga. In addition to these two specimens a subadult was examined in the house of a local resident of Alter do Chao. Both turtles were caught in unbaited fyke nets in clear water igarape streams 2 m deep in areas with submerged aquatic vegetation. These records extend the range of this species 24 km upstream from Santarem in the Rio Tapajos and document their natural occurence in clear water streams. George Rebelo also identified skeletal material and tracks of nesting females in the same area.

SERPENTES

CORALLUS ENYDRIS (Deer Snake). BRAZIL, SÃO PAULO: Iguape: Estacão Ecológica da Juréia-Itatins (24° 32' S, 47° 15' W). On a forest trail bordering the Rio Verde 400 m from the sea, 09 December 1988. Female 100 + 28.5 cm. H. G. Bergallo, C. Strussmann and C. F. D. Rocha. Verified by Ivan Sazima. Museu de Historia Natural, Universidade Estadual de Campina (ZUEC 0723). First documented record for São Paulo State, extends the range to southern Brazil. The subspecies *C. e. enydris* is distributed in Southern Venezuela, Guianas, Ecuador, Peru, Bolivia, Northern, Western (Peters and Orejas-Miranda, 1970. Bull. U. S. Nat. Mus. 297:72-73; Cunha and Nascimento, 1978. Mus. Par. Emilio Goeldi, Publ. Avul. 31, 218pp) and Northeastern Brazil (Cordeiro and Hoge, 1973. Mem. Inst. Butantan 37:261-290) and the subspecies *C. e. cookii* occurs in Central America (Nicaragua to Colombia, Northern and Central Venezuela, Trinidad and Windward Islands) (Peters and Orejas-Miranda, 1970).

DIADOPHIS PUNCTATUS REGALIS (Regal Ringneck Snake). USA: NEVADA: Clark Co: Spring Mountains, Pine Creek Canyon, ca. 1500 m, 17 September 1967. R. Clark. Verified by W. Pratt. UNLV Natural History Museum (UNLV R-5229). A second specimen (DOR) found on the SE edge of the Spring Range, 0.3 km W of Mountain Springs, 1612 m. October 1988. B. Hardenbrook. Specimen photographed; not preserved. Verified by R. Marlow. A third specimen found in the McCullough Mountains, 823 m. 30 April 1989. D. E. Delaney. Verified W. Pratt. (UNLV R-6082). The first reported specimen from Clark County. A specimen (LMNRA#613) was previously reported from Boulder City (Schwartz, Austin, & Douglas 1978, Biota of Lake Meade National Recreational Area. National Park Service/Cooperative National Park Resources Studies Unit LAME Tech. Report #2, 72 pp.), but is no longer in the LMNRA collection; it was deaccessioned in 1983. The exact locality, "Boulder City," is questionable, although occurrence of this species there is possible. The three records reported herein may actually be the first verifiable specimens from Clark County. They extend the known range ca. 125–175 km SSE of Rainier Mesa, Nevada Test Site (Tanner 1969, Great Basin Nat. 29:31–34), ca. 200 km SSW Caliente and Beaver Dam Wash, Lincoln County, Nevada (Tanner 1952, Great Basin Nat. 12:63–64; ; Banta and Frantz, 1957, Herpetologica 13:192), ca. 150–175 km SW Figure 4 Canyon, Virgin Mountains, Mohave County, Arizona (Soderquist and Middlebrook 1984, Herpetol. Rev. 15:115), ca. 155–190 km W 209 Mile Canyon, Grand Canyon National Park (Johnson and Carothers 1983, Herpetol. Rev. 14:28), ca. 85–140 km NNW of Fort Mohave, Arizona (Fowlie 1965, Snakes of Arizona, Azul Quinta Press, Fallbrook, California), and ca. 115–165 km NW of Kingan, Arizona (Lowe 1964, The Vertebrates of Arizona, Univ. Arizona Press. p. 169.).

LYCODON BUTLERI (Butler's Wolf Snake). THAILAND: KRABI PROVINCE. 18 July 1990. Merel J. Cox. Verified by Jarujin Nabhitabhata. Thailand Institute of Scientific and Technological Research, Ecological Research Department (TNRC 52 3852). This specimen was purchased from a dealer in Nakhon Si Thammarat Province who had obtained it from a hunter in neighboring Krabi Province in southern Thailand. This is the first record of this species in Thailand.

Submitted by **MEREL J. COX**, 695/17 Pracharaj Road, Soi Homhual, Bangkok 10800, Thailand ●

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). MÉXICO: JALISCO: Puerto Vallarta. 21 February 1990. Harold A. Dundee. Specimen found DOR on sidewalk of hotel grounds that were planted with various exotics. Verified by James R. Dixon. UNAM MZFC-04754. New state record. Nearest previous record at Rosario, Sinaloa is ca. 245 km N of Puerto Vallarta; more distant records lie eastward in Querétaro and southward in Guerrero (Dixon and Hendricks 1979, Zool. Verh. [173]: 1-39).

TANTILLA NIGRICEPS (Plains Blackhead Snake). NEBRASKA: Gosper Co: 6 km S & 2 km E Lexington. 9 October 1990. M. M. Peyton. Verified by John D. Lynch. Nebraska State Museum (NSM uncat. — Lynch will supply number to JTC). New county record and the most easterly collection for the species in Nebraska; only the second recent specimen collected within the state (Lynch, 1985, Annotated list of Amphibians and Reptiles in Nebraska. Transactions of the Nebraska Acadamy of Science).

Submitted by **MARK M. PEYTON**, Gothenburg Public Schools, 1415 Avenue G, Gothenburg, NE 69138, USA ●

DISTRIBUTIONAL RECORDS FOR TURTLES AND LIZARDS FROM NORTH KOREA

Locality data for reptiles inhabiting the northern half of the Korean Peninsula (Democratic People's Republic of Korea) have long remained unknown to wide publicity. Recently all the available information on the distribution of snakes in North Korea was summarized by Szyndlar and O (1987). Regarding turtles and lizards, the last paper covering the area (apart from a few publications in Korean language) was that of Shannon (1956). The aim of the present notice is to bridge this gap.

The following list of localities is based on specimens stored in the Zoological Institute of the Korean Academy of Sciences on Pyongyang (ZIP). The list does not include *Chinemys reevesi* and *Chelonia mydas* that, although present in the Pyongyang collection, are not labelled and therefore their localities remain unrecognized. A few specimens belonging to the collection of the Institute of Systematic and Experimental Zoology of the Polish Academy of Sciences in Cracow (ZZSiD), unless they were described by Szyndlar (1984), are also listed.

A number of the listed reptiles possibly were discussed in Won's (1971) monograph of the Korean herpetofauna. However, prior to 1984 the herpetological specimens from the Pyongyang collection were not catalogued and it is impossible to determine which of them were previously described. Taking into consideration that North Korea is an utterly strange area to most herpetologists, the locality names are accompanied by geographic coordinates.

TESTUDINES

TRIONYX SINENSIS (Chinese Softshell): NORTH PYONGAN: Island Unmu-do (30°24'N, 125°07'E). 15 May 1967. (ZIP 37).

DERMOCHELYS CORIACEA (Leatherback): SOUTH PYONGAN: Pyongwon county. 17 November 1960. (ZIP uncatalogued). This specimen is most likely identical with that recorded by Tong and Yon (1961).

SAURIA

EUMECES COREENSIS: NORTH PYONGAN: Island Sinmi-do (39°33'N, 124°54'E). 29 June 1965. (ZIP 41). Island Chongju (39°41'N, 125°13'E). 25 July 1979. (ZIP 42 and 43).

SCINCELLA REEVESI (Reeves' Skink): RYANGGANG: Paegam (41°34'N, 128°48'E). 25 (sic) January 1968. (ZIP 44 and 45). 25 (sic) February 1968. (ZIP 46-48). KANGWON: Ichon (38°28'N, 126°53'E). Date unknown. (ZIP 195 and 196). Kumgang-san (38°39'N, 128°07'E). 20 August 1969. (ZIP 149 and 150).

EREMIAS ARGUS (Mongolian Racerunner): PYONGYANG CITY: Taesong-san (39°04'N, 125°50'E). 17 May 1969. (ZIP 194). KANGWON: Cholwon (38°20'N, 126°53'E). Date unknown. (ZIP 130). Kumgang-san (38°39'N, 128°07'E). 22 July 1969. (ZIP 56 and 57). CHAGANG: Kae-gogae (40°25'N, 126°21'E). 18 May 1987. T. Tomek. (ZZSiD 686).

TAKYDROMUS AMURENSIS (Amur Grass Lizard): RYANGGANG: Paekdu-san (42°00'N, 128°05'E). 20 May 1970. (ZIP 132). NORTH HAMGYONG: Chilbo-san (41°02'N, 129°36'E). June 1978. (ZIP 131). NORTH HWANGHAE: Kumchon (38°09'N, 126°29'E). May-August 1968. (ZIP 274-282). 2 August 1969. (ZIP 124 and 125). SOUTH HWANGHAE: Haeju (38°02'N, 125°44'E). 1966. (ZIP 133-136). Suyang-san (38°09'N, 125°42'E). 14 October 1984. Z. Szyndlar. (ZZSiD 679-684). KANGWON: Ichon (38°28'N, 126°53'E). Date unknown. (ZIP 197-206). 1968-1969 9207-224). Kumgang-san (38°39'N, 128°07'E). 20 August 1969. (ZIP 146-173). Sambang-ri (38°43'N, 127°21'E). 2 August 1964. (ZIP 225-251). 13 June 1973. (ZIP 178-180). KAESONG CITY: Kaesong (37°58'N, 126°33'E). 1969. (ZIP 139-145). Pagyon-pokpo (38°04'N, 126°34'E), 16 October 1984. Z. Szyndlar. (ZZSiD 685).

TAKYDROMUS WOLTERI (Mountain Grass Lizard): PYONGYANG CITY: Taesong-san (39°04'N, 125°50'E). 17 May 1969. (ZIP 183-193). KANGWON: Kumgang-san (38°39'N, 128°07'E). 20 August 1969. (ZIP 148). Sambang-ri (38°43'N, 127°21'E). 2 August 1964. (ZIP 252 and 253). 20 August 1969. (ZIP 148, 174-177).

NEW COUNTY RECORDS FOR AMPHIBIANS AND REPTILES OF EAST TEXAS

These specimens represent new county records (Dixon 1987. Amphibians and Reptiles of Texas. A&M Uni. Press, College Station. 434 pp.) for five species of amphibians and reptiles from two counties of East Texas. Voucher specimens are deposited in the University of Texas at Yler (UTT) vertebrate collection. All specimens were collected by one or more of the authors and verified by Neil B. Ford.

ANURA

HYLA CINEREA (Green Treefrog). Van Zandt Co: On Madis Farm W. of Edom off FM 2339, 4.3 km off Hwy. 279. 4 August 1988. (UTT 568, 569). Specimens found at night near the edge of a pond.

HYLA CHRYSOSCELIS/VERSICOLOR (Cope's Gray Treefrog/Gray Treefrog). Van Zandt Co: On Madis Farm W. of Edom off FM 2339, 4.3 km off Hwy. 279. 21 October 1988. (UTT 570, 571). Specimens found during daylight in a wooded area.

TESTUDINES

STERNOTHERUS ODORATUS (Common musk turtle). Van Zandt Co: On Hwy.

80 W., 3 km off Hwy. 19 N. 4 June 1989. (UTT 575). Found on the shore of a pond.

SERPENTES

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). Henderson Co: 12.2 km S. of Brownboro on Hwy. 607. 15 July 1988. (UTT 567). Found DOR. Extends range eastward becoming adjacent to Smith and Van Zant counties, both recorded containing subspecies *Elaphe g. guttata* (corn snake).

HETERODON NASICUS GLOYDI (Dusty Hognose Snake). Henderson Co: On FM 317, 10 km off Hwy. 31. 26 May 1989. (UTT 574). Found DOR.

NEW COUNTY RECORDS OF AMPHIBIANS AND REPTILES FROM TEXAS

Dixon (1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.) provided current distributional maps for the state's 204 species of amphibians and reptiles. Additional county records have since then been reported (Calaway et al. 1988. SSAR Herp. Review 19:19; Carignan 1988. ibid. 19:60; Cheatham 1988. ibid. 19:19; Cobb and Cobb 1991. ibid. 22:25; Corder 1988. ibid. 19:21; and McAllister 1988. ibid. 19:61-62).

In this note we list nine new county records for Texas (Dixon op. cit.). All specimens have been deposited in the Arkansas State University Museum of Zoology (ASUMZ). Specimens were collected by the authors and identifications were verified by S.E. Trauth. Collections were conducted under the authority of the Texas Parks and Wildlife Department Scientific Permi (085) to SET.

ANURA

PSEUDACRIS CLARKII (Spotted Chorus Frog). Coke Co: 6.4 km E FM 2034, 38.5 km N Jct US 87 and FM 2034. 21 April 1988. (ASUMZ 10717). Crockett Co: 20.0 km S Barnhart on State Hwy 163. 22 April 1988. (ASUMZ 10718, 10719).

CAUDATA

AMBYSTOMA TEXANUM (Smallmouth Salamander). Brown Co: 20.7 km W Comanche on US 67. 23 April 1988 (ASUMZ 10749).

SAURIA

SCINCELLA LATERALIS (Ground Skink). Coke Co: 30.4 km N Jct FM 2034 and US 87 on FM 2034. 21 April 1988. (ASUMZ 10995).

OPHISAURUS ATTENUATUS ATTENUATUS (Western Slender Glass Lizard). Brown Co: 20.7 km W Comanche on US 67. 23 April 1988. (ASUMZ 10993).

SCELOPORUS OLIVACEUS (Texas Spiny Lizard). Schleicher Co: 34.8 km W Jct FM 2129 and US 277 on FM 2129. 22 April 1988. (ASUMZ 10788).

UROSAURUS ORNATUS ORNATUS (Eastern Tree Lizard). Schleicher Co: 34.8 km W. Jct FM 2129 and US 277 on FM 2129. 22 April 1988. (ASUMZ 10726, 10727).

SERPENTES

LEPTOTYPHLOPS DULCIS DULCIS (Plains Blind Snake). Runnels Co: 5.7 km E Ballinger on US 67. 23 April 1988. (ASUMZ 10738, 10739).

SALVADORA GRAHAMIAE LINEATA (Texas Patchnose Snake). Eastland Co: 7.5 km S Jct Interstate 20 and State Hwy 206 on State Hwy 206. 20 April 1988. (ASUMZ 10731).

CAIMAN CROCODILUS IN THE "CAATINGA" OF SOUTHEASTERN PIAUÍ, BRAZIL

The Caatinga is a vast semi-arid region encompassing most of northeastern Brazil, *ca.* 35°–45° W. longitude and 3°–16° S. latitude (Reis 1976). This area is the largest dry region within the tropics (Markhan 1972; Reis 1976) and is bordered by much more mesic habitats.

Most of the Caatinga receives less than 500 mm of rain per year, although some areas receive more than 1600 mm, with great annual variation. Periods of severe drought may be followed by floods. There is a large degree of endemism among the plants (Lima 1960; Hayashi 1973; Hayashi and Numata 1976).

The herpetofauna of the Caatinga has been well-studied (Vanzolini *et al.* 1980), although several new taxa have been described recently (Rodrigues 1984, 1986, 1987, 1988; Manzani and Abe, *in press*). The only major reptile group considered absent is the Crocodilia (Vanzolini *et al.* 1980), although populations of broad-nosed caiman (*Caiman latirostris*) and dwarf caiman (*Caiman palpebrosus*) are recorded from the Rio São Francisco basin, which bisects the region. Common caiman (*Caiman crocodilus*) is known from the Rio Parnaíba, at its northwestern limit (Carvalho 1955). The Rio São Francisco and the Rio Parnaíba are the only perennial rivers in the region.

Southeastern Piauí lies near the western limit of the Caatinga, but climate and vegetation are typically xeric (Emperaire 1987). The region is drained by the Rio Piauí basin, which contours the Serra de Capivara massif and eventually joins the perennial Rio Parnaíba. The Piauí and its tributaries are all intermittent during the dry season and are composed of scattered ponds and lagoons along the sandy bed. The rivers run only during the rare heavy rains, which also cause floods.

Some tributaries of the Piauí (riacho São Domingos, Baixão da Boa Esperança) form large lagoons which are perennial, although subject to wide variations in water level. In one of these, Lagoa do Muquem (08°24'30"S, 42°22'20"W), we discovered a population of caimans (*Caiman crocodilus*) in December 1986, based on information obtained from natives.

A night count on 12 December 1986 showed 31 caimans over the southern half of the lagoon, mainly along the margins with denser vegetation. The reptiles were extremely wary and difficult to approach, probably as a result of persistent hunting. Estimated length of individuals sighted ranged from 60 to 80 cm TL.

Along the margin, at a place where the Caatinga was near the water, we found a pod of 30 small juvenile caimans, probably a few weeks old. Some of them were emerging from the bushes and moving toward the water, but no adults were

sighted. This pod probably hatched at the end of the dry season.

Another population of caimans was located in an artificial lake at Fazenda (ranch) Veneza (08°45'S, 42°16'W). This lake was constructed about 20 years ago by damming a tributary of the Piauí, which is 7 km downriver. It usually covers several hundred acres and may have a depth of ten meters, but during drought it may dry up completely. On such occasions the caimans are said to aestivate buried among the debris of a banana orchard at the base of the dam. This seems to be a favorite resting place, according to the landowner.

The caimans reportedly reached the lake on their own, walking or swimming when the Piauí became flooded. It is known that crocodilians will walk long distances over land in search of water and *C. crocodilus* is no exception (Guggisberg 1972; Gorzula 1978; pers. obs.).

In the lake, caimans were concentrated along the narrow, long bay with shallow water and abundant aquatic vegetation. A night count showed 13 caimans along the lake's shore. All individuals were small, 60–90 cm in total length. During the previous day a larger caiman, about 110 cm Tl, was found resting among the margin's bushes.

Caimans in southeastern Piauí are today a relic species restricted to the larger and more perennial water collections left in a xeric, semi-arid habitat. Rock paintings, dated from 6000 to 10000 years B.P. in several archeological sites in the Serra da Capivara massif, show caimans together with other water-loving species, such as capybaras (*Hydrochaerus hydrochaeris*) and marsh deer (*Blastocerus dichotomus*), indicating a more aquatic environment existed at that time. (Pessis 1987). With the recent progressive aridity, these species became extinct. The caimans managed to survive and even colonized newly formed areas of habitat. A similar but more extreme situation occurred in the Sahara, where several populations of Nile crocodiles (*Crocodylus niloticus*) survived in isolated lakes and ponds in the desert (Guggisberg 1972).

The caimans remaining in the Caatinga of southeast Piauí are now endangered due to persistent hunting and may soon be among the species left only as rock paintings.

ACKNOWLEDGMENTS

Our research was part of a faunal survey funded by the Fundação Museu do Homem Americano (FUMDHAM and CNPq). We wish to thank Niede Guidon for all the help and encouragement. Senhor Angelo received us in his home and permitted our work at Fazenda Veneza. Nilson Parente helped in field work. Dr. Samuel s. Sweet reviewed an earlier version of the manuscript and made useful suggestions.

BOOK REVIEWS

Cytogenetics of Amphibians and Reptiles, by Ettore Olmo (ed.), 1990, Birkhauser Verlag, 270 pp.

Cytogenetics, the study of chromosomes, is an old field of research with a venerable history. It is fun to imagine the excitement that must have been felt by early workers who realized for the first time that chromosomes are packages of genes that can be counted and measured, and whose intricate behaviors during mitosis and meiosis can be observed or reconstructed. To many of these workers, cytogenetics seemed to offer the most direct route to understanding how organisms come to be: not only how they reproduce, but how they develop and how they evolve. In fact, this point of view is still valid in many respects, but the number of workers choosing to pursue this approach has been steadily dwindling.

The reason for the current unpopularity of cytogenetics is due to at least two factors. First, the job of using cytogenetics to study development or evolution has turned out to be much more difficult (and time-consuming) than ever imagined. Secondly, the more recent field of molecular biology has made an end-run around classic cytogenetics, effectively elbowing chromosomes aside to get directly at the DNA itself.

Nevertheless, cytogenetics has always had its staunch adherents, ranging from those who strive to incorporate molecular methodologies to those who are simply "in love" with chromosomes and won't give them up. Whatever the reason

for sticking with chromosomes, cytogeneticists are faced with new challenges centered on the question: "What good is the study of chromosomes?" This book, edited by E. Olmo, gives us a chance to take stock of what recent cytogenetics has to offer, at least as applied to certain organisms.

The book, as the editor points out, grew out of a symposium held at the First World Congress of Herpetology in Canterbury UK in 1989. Its goal is to present an overview of the current status of cytogenetics as applied to amphibians and reptiles. The book is truly international in scope, and contains 18 chapters divided among two sections, depending on whether they concern amphibians (10 chapters) or reptiles (8 chapters).

The amphibian section contains contributions from many of the most familiar workers in the field, including Morescalchi, Schmid, Macgregor, and Mancino, as well as some less familiar authors and their coworkers. This section begins with a creative essay by Morescalchi on the use of cytogenetics in sorting out the relationships among the lissamphibians. For those readers familiar with Morescalchi's writings, this is a typical example of his imaginative, broad-stroke reconstruction of the "Big Picture," using everything from genome size and metabolic rates to heterochrony and exploding karyotypes. I found it interesting and fun to read, but to be taken with a healthy grain of salt. Schmid and Macgregor also present typical products, Schmid with a competent overview of banding studies in amphibians, and Macgregor with a summary of the latest results of his research program on development and cytogenetics in *Triturus*. Two of the most important chapters in this section are those by Mancino and Kohno et al., who discuss powerful new approaches to cytogenetic studies.

The reptile section of the book includes chapters by King, Olmo et al., Mortiz, Becak et al., and several others. King's chapter is a thorough and convincing approach to the problem of origin of the reptiles of Australia, emphasizing the importance of using independent data sets to try to reconstruct biogeographic history. Mortiz presents evidence from his studies of gekkonid cytogenetics concerning the process of sex chromosome evolution, and argues convincingly that this is an ideal group in which to address this question. The chapter by Olmo et al. presents a useful compilation of cytogenetic information on lacertids, but suffers from the authors' apparent lack of confidence in using this wealth of information to make their own phylogenetic hypotheses.

Weaknessess of the book include the poor taxonomic representation (e.g. caecilians are hardly mentioned and only two salamander groups are focused on: *Triturus* and hynobiids), and the almost complete lack of phylogenetic analyses using current methodologies. Another, but less important, weakness is that the book is full of mistakes in spelling and English.

Overall, I found the book a welcomed, if somewhat disappointing, contribution to cytogenetics awareness. I think it will win few if any converts to the field, although I am sure the authors would counter that that was not the purpose of the book. On the other hand, it does serve the purpose of helping to keep cytogenetics alive despite unfavorable odds. I predict that cytogeneticists who "keep the faith" and continue to struggle to integrate new methodologies into their work will be paid off in the end with quantum leaps towards understanding genome structure and function in development and evolution.

The Alligator Snapping Turtle: Biology and Conservation, by Peter C. H. Pritchard. 1989. Milwaukee Public Museum, 800 W. Wells St., Milwaukee, WI 53233-1478, USA, xii + 104pp., 20 color and 14 b/w photos, 1 map. Soft cover only, $29.95 + $2.50 shipping ($3.50 foreign); Wisconsin residents add $1.50 sales tax.

On a still morning in April 1990, on a bank of the Apalachicola River, FL, I laid motionless in the sand and watched what, for a brief moment, seemed to be an apparition from the Mesozoic. It was a female alligator snapping turtle, *Macroclemys temmincki*, slowly kneading her way from her nest in an attempt to conceal her still-moist eggs from predators. Mike Ewert, with whom I had just begun a study of the species' nesting ecology, described her as antediluvian, and truly she appeared to be so. The alligator snapping turtle is not only one of the largest but also one of the most archaic-looking of modern reptiles; in fact, its superficially striking resemblance to the Triassic *Proganochelys* (Gaffney 1990) is almost eerie. But surprisingly, as Pritchard reminds us in this book, this is anything but a primitive turtle, instead being a highly derived form in many respects. The largest living fresh-water turtle in North America, the alligator snapping turtle is nonetheless one of the most rarely seen (except by knowledgeable fishermen) and, consequently, one of the most poorly studied by biologists.

Because of its size and former abundance in the rivers of the southeastern United States, this turtle traditionally has supported one of the largest commercial harvests of any North American reptile. The species has certainly declined in abundance as a result, but no one really knows to what extent. Consequently, and despite the absence of sound population data, many people believe that the species is now in peril. One such person is renowned chelonian biologist Peter Pritchard, who persuaded the World Wildlife Fund (WWF) to support his proposal to gather preliminary information about the species and to determine its survival status as best he could within funding limitations. Weighing his options for the latter, Pritchard eschewed a classical field study ("the turtles were too hard to find" and "would give no useful insight into long-term trends") in favor of interviewing professional turtle trappers and knowledgeable field biologists. As he became increasingly disturbed about the species' survival prospects, he decided to prepare a formal petition to the U.S. government to designate this turtle as a Threatened species.

In this slender volume, which is a reworked version of his final report to WWF, Pritchard presents the results of his survey, along with a review of other biological information pertinent to this monotypic genus. Included are chapters on relationships and comparisons (chiefly a comparison of the Platysternidae and Chelydridae, a synopsis of fossil chelydrids, and a review of *Chelydra* life history), nomenclatural history, morphology (principally skeletal), distribution (including a summary of fossil *Macroclemys*), geographic variation (i.e., areas in need of investigation), size (mostly a discussion of record size turtles), diet and feeding mechanism, reproduction, movements, husbandry, exploitation, population status and trends, and conservation recommendations. Some chapters will interest but a few specialists, whereas others have broader appeal.

In reviewing this book, I feel it is important to point out not only what the book is, but also what it is not. It is not the final summation of a scientific study. There are no graphs, no tables of data, no statistics. Instead, Pritchard's goal was to "assemble available information — published and unpublished — on an extraordinarily inter-

esting chelonian that, for some reason, had been the subject of few field studies." Pritchard himself characterizes his book as an "odd" yet hopefully comprehensive view of what we know about *Macroclemys*.

My overall impression of the book is of having read a nearly endless series of anecdotes loosely woven into a species' biography. Nonetheless, for many aspects of this turtle's biology, this is all we have, and future students of the genus will owe their gratitude to Pritchard for compiling these widely scattered tidbits into a single source. The ecological chapters are weak, but so is our data base for the species. In matters of morphology, Pritchard is not hesitant to suggest possible functions (e.g., for carapacial keels and supramarginal scutes), and, although I generally found his explanations believable, they should not go unchallenged. For example, if the reduced plastron of chelydrids is a feature associated with the long neck and head-thrusting mode of feeding, as Pritchard suggests, then why do we see no sign of plastral reduction in other turtles, such as the emydid genus *Deirochelys*, that possess a similar trophic apparatus? Perhaps the reduced chelydrid plastron instead relates to a unique locomotor pattern or other function. Likewise, some of Pritchard's speculations about behavior patterns are weak in substance. To suggest that a female *Macroclemys* would find the embrace of a male twice to three times her size "more terrifying than erotic" is too anthropomorphic for me, and is an especially surprising statement coming from a man who shares a spousal relationship of similar proportions.

The chapter on distribution offers a state-by-state account of all records that Pritchard could locate and points to the need for scientific confirmation of records in many of the gaps. Unfortunately, the distribution map was cropped too closely to include the northernmost record (Rock Island Co., IL) given for the species. Although he remarks that no specimens are known from the St. Marks River system in the Florida panhandle, he notes (within a discussion of the Ochlockonee River system to the west) a specimen from the Wakulla River, which is confluent with the St. Marks. The year of collection is given for only a few of the listed museum records (compiled by J. Iverson); it surely was available for many more and could have provided an additional perspective.

The final and perhaps most important chapters of the book deal with exploitation of the species, its status, and recommendations for study and conservation. Pritchard's interviews successfully document locally heavy harvest by commercial fisheries, mostly in the 1960's and early 1970's, with probable depletion of local populations, particularly in southern Louisiana. With the recent decline of these fisheries, however, it would seem that the greatest long-term threat to the species may now be habitat degradation, chiefly via pollution.

As a result of his interviews, Pritchard submitted in 1983 a formal petition, accompanied by a copy of his preliminary report, to the U.S. Fish and Wildlife Service to list the alligator snapping turtle as a Federally Threatened species. Following governmental review, the petition was rejected, at least in part because of the lack of quantified data about past and present numbers and the level of exploitation. Of course, these data simply do not exist. In his book, Pritchard states his belief that the decision was largely political. Though that may be, I myself do not find the evidence that he presents in his book as making a compelling case that this species is likely to become endangered throughout a substantial portion of its range in the foreseeable future. I am convinced, however, of the need for a range-wide cooperative federal/state status survey of the species and the condition of and threats to its habitat. In a paper published after Pritchard's book had gone to press, George (1988) noted that this turtle is legally protected in seven states (including Florida, which allows limited harvest) and reported that a state-funded survey had been instigated in Louisiana. Until that survey is completed, the Louisiana Department of Wildlife and Fisheries should enact an immediate moratorium on the take of this species.

The physical nature of the book itself deserves mention. The large, bold print and glossy pages, printed in two-column (but surprisingly not right-justified) format, make for easy reading. Both color and black and white photographs are generally clear and of high quality; they presumably are at least partly responsible for the somewhat high price for such a slim book. However, for those of you who decide to spring the $30, I suggest you request a 90-day warranty. My copy literally self-destructed despite careful handling. By the time I had reached page 11, most of the preceding pages had already fallen out, and the binding was separating from the remainder. I called the publishers, who graciously offered to replace the copy and said they would do so for any defective book, although they had received no other complaints after having sold hundreds of copies already. I also learned the sad news that, because of budget cuts, this is the last book that MPM will publish for the foreseeable future.

For the size of the book, the index is extensive, including almost every noun mentioned, from broom handles to Antoine's Restaurant. The Literature Cited is thorough; a quick check of my own card file showed that the only references I list for the species that are not cited by Pritchard are either relatively cursory to his theme or too recent for inclusion. He in fact may go overboard in citing references; I question his practice of citing unpublished data from grant proposals and manuscripts, even though he gives appropriate credit.

With one exception, proof-reading seems to have been reasonably thorough; I found only about a dozen typographical errors. However, I was frustrated by the complete omission of a section of text of considerable length (two galley pages, copies available from PCHP) from the review of fossil *Macroclemys*, including reference to *M. auffenbergi* (the appropriate reference is included in the Literature Cited). Other minor errors reflect haste or carelessness - e.g., the incorrect listing of a contributor as Dr. and the placement of Earlham College in Illinois. Chelonian biologists are accustomed to the various applications by different authors of the words "costal" and "pleural" to either bones or epidermal laminae, but Pritchard employs the terms inconsistently even within the same chapter. After telling us that the specific epithet of *Macroclemys* appropriately ends in a single rather than a double "i," he then goes on to use both spellings throughout the book. Likewise, his discussion of size regularly alternates between metric and English measurements. A more thorough final bit of editing also would have reduced numerous cases of redundancy.

For professional and amateur herpetologists, agency personnel and conservationists who may have a need for information about the alligator snapping turtle, this book surely will be the most efficient means of gaining access to the pertinent literature. But it will be a long time before anyone will produce a *Macroclemys* biography that will approach the scale of knowledge contained about *Trachemys scripta* in Gibbons' (1990) recently published monograph. Extensive studies about North America's largest living fresh-water turtle are sorely needed.

Finally, a personal note: Peter Pritchard should be applauded for his efforts to draw public and scientific attention to the conservation of our world's

imperiled herpetofauna. It is an activity in which all members of our professional societies should urgently participate. The need has never been greater.

Tallahassee, FL 32308, USA

Atlas Anima, volume 3, Amphibia and Reptilia, by Hiroshi Aramata. 1990. 375 pp., clothbound. Heibonsha Limited, Publishers, 5 Sanbancho, Chiyodaku, Tokyo 102, Japan. Price ¥11,300 (about US$87) plus postage.

This book is unique, for there is nothing like it in any language. Mr. Aramata, one of Japan's most popular writers, is also an amateur naturalist. Over many years he has amassed a superb collection of the classic works on natural history, mostly published before 1900 and beginning with the 16th century. Because of the rarity of these books, which contain some of the most exquisite illustrations of animals ever produced, Mr. Aramata decided to share these treasures by writing a five-volume series entitled "Atlas Amina." The amphibians and reptiles are covered in volume 3.

Following an historical review of the classification of amphibians and reptiles and a discourse on methods for their illustration, the book is organized into chapters arranged according to family or groups of related families. Each chapter provides discussions about the origins of scientific and common names of that family, and examples of the use of amphibians and reptiles in mythology, religion, Egyptian hieroglyphics, popular writing, sculpture, and folk tales, to mention only a few areas. All topics are profusely illustrated with black-and-white photographs and drawings copied from original works. The coverage is broadly international. The text, of course, is mainly in Japanese (although each chapter is introduced with familial terminology in Japanese, Chinese, Latin, English, French, German, Dutch, and Russian), but most figures are self-explanatory.

The main value of this book to herpetologists are the colored plates—about 450 of them, many of which have multiple figures! These are taken from dozens of classic authors such as Bonaparte, Cuvier, Duméril, Fayrer, Maki, Roesel von Rosenhof, and Sowerby and Lear. Each animal is identified by Latin, Japanese, and English names and is carefully referenced to its source. One of the book's indexes, which lists all sources of illustrations, conveniently permits the reader to find every plate in this volume that has been reproduced from a particular title. For example, we find colored illustrations from Albertus Seba's colossal atlas, the famous "Thesaurus" of 1734-1765, on 21 different pages. Probably no more than a few dozen colored copies of Seba exist and since many of his figures served as types for new species described and named by Linnaeus and other early authors, the scientific value of these reproductions is readily apparent.

Another example is Conrad Gessner, who in 1551-1587 published the first comprehensive illustrated books on zoology. Colored copies are very rare, since before the invention of color printing each copy had to be individually handcolored and only the richest patrons of that era could afford them. Mr. Aramata has reproduced Gessner's chameleon, the very figure chosen as the logo of the World Congress of Herpetology, but here we have it in full color.

From Andrew Smith's "Zoology of South Africa" there are 19 plates; from H. R. Schinz's atlas, 23; another 11 are from John Gray's "Illustrations of Indian Zoology"; a like number from Ramón de la Sagra's famous work on Cuba, which contains some of the finest handcolored plates of lizards and other reptiles ever executed; 14 from John Holbrook's "North American Herpetology"; and so on. As for Seba, many of the specimens illustrated by these authors served as types for new species described by them or others.

The quality of color reproduction is outstanding and true to the originals. One minor complaint is that several of the largest illustrations had to be spread across facing pages, thus losing part of the figure in the binding margin; it would have been preferable to use foldout pages for these illustrations.

The volume concludes with seven indexes: Sources of color plates; books mentioned in the text; names of authors and artists, with biographical information; indexes to Japanese, Latin, and English names; and a general index. There are also two extensive bibliographies which separately list works in Japanese and non-Japanese languages. Several of the indexes and bibliographies are extensively annotated.

The great value of having all of these classic illustrations of amphibians and reptiles under one cover cannot be overemphasized. The choice of which plates to reproduce displays good judgement, both from artistic and scientific points of view. Mr. Aramata and his editorial team are to be congratulated on this magnificent production. For most herpetologists this book will be their only opportunity to appreciate the remarkable artistic and printing capabilities of yesteryear which, in many respects, are superior to those of today. We have been spoiled by photography, for the camera often cannot capture the subtle shading made possible by genuine lithography, the "ideal" postures or whimsical expressions of some drawings, and certainly not the mythical dragons and beasts created with great imagination from the shriveled carcasses brought to European naturalists by travellers from distant lands.

This book faithfully reflects the best work of a vanished era when natural history artists were highly respected and liberally supported, and when they sometimes even wrote the books themselves because they were so knowledgeable about their subjects. Mr. Aramata's remarkable compilation allows us to appreciate their contributions as never before and to mourn their virtual disappearance.

art for alligators

Melissa Shoemaker

THE PROGRAM

The American alligator is a prominent feature of Florida's landscape, of which about 30 percent is wetland. The species has been exploited commercially both directly and indirectly; it has been killed, caricatured and held captive in roadside zoos. If there is a single animal which symbolizes Florida, it is the alligator.

The Florida Game and Fresh Water Commission has made sure that direct exploitation of alligators involves some restitution to the population. License and tag fees from the legal take of alligators currently bear most of the burden for research and management on the species. Poaching is no longer a threat to the alligator. Indirect exploitation — wetland habitat degradation or even commercialization of its name or image — results in no return to the species. Wetland habitat destruction is now its nemesis.

Howard Suzuki

Gregg Murray and the Florida Wildlife Federation offer limited edition prints and posters each year for the purpose of raising funds to support research on this natural treasure. Purchasers will have the option to get the same numbered print each year. The proceeds of the project will support the alligator research program established in the Department of Wildlife and Range Sciences of the University of Florida. The hallmark of that effort has been an interdisciplinary approach involving a variety of University and agency researchers. The financial support will include scholarships and fellowships to deserving students.

THE ARTIST

My favorite medium in art is scratchboard. I have been working with scratchboard for seventeen years. Scratchboard is a heavy paper—base artboard with a clay coating that is white in its original state. Black india ink is painted over the clay surface and dried. The ink is scratched away using a sharp tool to produce the image.

I have developed a color-technique to stratchboard, which is done by applying color into the scratches and carefully buffing any excess color off the black. The application of color has developed into a beautiful approach to the medium. Actually, I believe that this technique offers some of the best of both 'worlds' — the textures and detail of an etching, combined with the realism and beauty of color.

I currently make my home in central Florida near the Harris chain of lakes. I am a member of the Society of Animal Artists. I have received 'my share' of awards — most recently '88 Peoples Choice Award (1st Place) Ann Arbor, Michigan and '89 Best in Show (scratchboard) National Wildlife Art Show, Overland Park, Kansas.

BROKEN SILENCE

'Broken Silence' is the culmination of ideas derived from experiences that I've had in the field as a volunteer with biologists, working on alligator research, from the University of Florida. While checking an alligator nest, we found turtle eggs laid within the same nest. These eggs were from a species of turtle called the red-bellied slider. I've since seen these turtles peacefully resting with alligators on logs, in various waterways. I learned from my biologist friends that alligators larger than nine feet in length also feed on these turtles in Florida (if they can catch them!). It is this confrontation that has inspired my 'Broken Silence'.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi-and non-technical articles (original research should be submitted to the **Journal of Herpetology** - see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letter from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double spaced, on 8.5 X 11 inch paper, and should be sent in duplicate. We encourage submissions on Macintosh disks, though we can also work with TEXT (ASCII) files submitted on 3 1/2" IBM compatible floppies. **Herpetological Review** is composed on a Macintosh SE/30 using Microsoft Word and Aldus PageMaker. Format your documents full-page width; we will fit to **HR** format. Unpublished photographs of an unusual nature or of uncommon amphibians or reptiles may also be submitted. These should be 8 X 10 inch black and white, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled lightly on the back of each print. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs solicited by the Editor will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising. Rates and copy information are available from the Advertising Manager. Fully formatted ads may be provided on 3 1/2 inch disks in several Draw or Paint formats. Contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

Society For The Study Of Amphibians And Reptiles

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (4 issues annually), **Herpetological Review** (4 issues annually), and occasional issues of **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1990

Student member.....$25.00*	Sustaining member.....$50.00*
Regular member.....$35.00*	Contributing member.....$75.00*
Institutional subscription.$60.00*	Life member..(see below)...$600.00*

***Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, draft on a US bank, or by Mastercard or Visa (include account number and expiration date of credit card). Life memberships may be paid in 3 consecutive payments

Subscriptions to Herpetological Review only are available for $12.00 annually. Subscriptions outside of the US require a surcharge of $8.00 for air delivery if airmail is desired. Subscribers to HR only are not members of the Society.

Catalogue of American Amphibians and Reptiles: subscription $15 annually ($3.00 air delivery surcharge if airmail is desired.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc., RFD 6 Box 1, Lawrence, KS 66046. Steve Meseraull, Printer. 1991 JOINT ANNUAL MEETING
of
THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
AND
THE HERPETOLOGISTS' LEAGUE

at

THE PENNSYLVANIA STATE UNIVERSITY
UNIVERSITY PARK, PENNSYLVANIA
6 -11 AUGUST 1991

Meeting Site

Penn State's University Park Campus is located in central Pennsylvania in one of the most attractive mountain areas in the East. The University and the adjacent community of State College are situated on a wide plateau, 1,200 feet above sea level, between forested ridges of the Allegheny Mountains. The area is noted for its outdoor recreational opportunities which include swimming, boating, hiking, camping, caving, and skiing.

Penn State is a comprehensive land-grant University composed of 10 schools and colleges. Approximately 37,500 students are enrolled at the University Park Campus.

All sessions and symposia will be held in meeting rooms at the Keller Conference Center and the Kern Graduate Building. These buildings are within easy walking distance of each other.

Accommodations and Meals

Dormitory housing is available with or without a meal plan. Camping facilities are available at Bellefonte KOA Campground 12 miles N of State College. Blocks of rooms have been reserved at the following State College Hotels that are within walking distance: The Nittany Lion Inn (1-800-233-7507), Days Inn Penn State (814-238-8454 or 1-800-325-2525) and the Imperial Inn (1-800-782-0716). Additional hotels, diverse restaurants, bookstores, art museums, and entertainment are all within several blocks of the meeting site. Food service will be available in the dormitories, the student Hetzel Union Building and many unique eateries in downtown State College - a 5 minute walk from campus.

Recreational Facilities

An outdoor running track at the Track and Field Stadium (free) and an indoor track at Rec Hall (free) are available. Facilities in Rec Hall include courts for racquetball, squash, weight room, exercise room and other features. The outdoor pool is $1.50 per person per day and the indoor pool is $2.00 per person per day. The ice skating pavilion is $2.75 for adults and $2.25 for children (skate rental is $1.25). All prices are subject to change.

Transportation to State College

State College is located at the junction of Rts. 322 and 26, 35 miles south of I-80, Exit 24. University Park Airport is a 10 minute drive; taxi service and limousine service are available to the campus and downtown State College. State College is also served by Greyhound and Trailways Buses. Parking is available at $3.00 per day in University parking structures and lots within a block of the residence halls and meeting buildings.

Board and Business Meetings

The SSAR-HL Liaison Committee Meeting will be held on Monday, August 5. The SSAR Board Meeting starts Tuesday, August 6, 1991 at 10:00 am. The HL Board Meeting begins Tuesday, August 6, 1991 at 1:00 pm. The SSAR Business Meeting is scheduled Thursday, August 8, 1991 at 4:30 pm. The HL Business Meeting is scheduled Friday, August 9, 1991 at 4:30 pm.

SYMPOSIA AND SPECIAL SESSIONS

On Wednesday, August 7, a symposium on "Habitat Acidity and Amphibian Decline" is scheduled. Contact W.A. Dunson, Penn State, for more information.

On Saturday and Sunday, August 9 and 10, a two-day symposium entitled "Captive Management and Conservation of Amphibians and Reptiles," organized by J. B. Murphy (Dallas Zoo) and J. T. Collins (University of Kansas), will be held. This is a special symposium to honor Roger Conant for his lifelong contributions to herpetology.

A special session on Women in Herpetology is being planned - Interested participants should contact Carla A. Hass, Penn State for more information.

There will be a Special Performance by the former "Ohio Herp Society Choir" on Friday evening at the Auction.

The SSAR Auction (Joseph T. Collins, Auctioneer) will be held on the evening of 9 August. Please bring or mail contributed items for this event to: Linda R. Maxson, Penn State.

Tours of nearby attractions in Hershey, PA (amusement park, chocolate factory, zoo, gardens, etc) will be offered if there is sufficient interest.

Plans for an exhibit of herpetological works of art are being formulated. If you are interested in participating in an art exhibit, contact S. Blair Hedges, Penn State.

There will be a live exhibit of amphibians and reptiles in Mueller Laboratory - a 5 minute walk from Keller Conference Center. For arrangements, write to John D. Groves, Curator of Reptiles, Philadelphia Zoological Gardens, 34th and Girard Ave., Philadelphia, PA. 19104.

Collecting Permits

For Pennsylvania collecting permits, write to Clark Shiffer, PA Fish Commission, 450 Robinson Lane, Bellefonte, PA. 16823.

Meeting Announcement

A detailed program and call for papers will be mailed separately in late February. Additional information can be obtained from Linda R. Maxson, Department of Biology, 208 Mueller Lab, University Park, PA, 16802, USA. (814) 865-4562. All interested persons are welcome to attend. Non-members should write to the meeting chair for registration forms.

SSAR BUSINESS

SSAR ANNUAL MEETING REPORT: NEW ORLEANS 1990

The 33rd Annual Meeting of the Society for the Study of Amphibians and Reptiles was held jointly with the Herpetologists' League, 5–9 August 1990. Harold Dundee was chair of the local committee hosting our visit to Tulane University, in New Orleans.

The SSAR Board of Directors held their annual meeting between 1000 and 1815 hours (mercifully, with a couple of breaks,including lunch) on Sunday, 5 August 1990, in the University Center. The Board Meeting was attended by 10 of 12 board members, editors of all publications but one, numerous committee chairs or their designees, and several interested members. During the meeting, the reports of the officers, editors, and committee chairs were discussed, as were several items of old and new business (see below).

PRESENTATIONS

The activities of the Annual Meeting began at 0900 hours, Monday, 6 August, with the Plenary Session where we were welcomed by Harold Dundee and then treated to the HL Distinguished Herpetologist lecture by Henry M. Wilbur. This lecture, entitled "Salient Features of Amphibian Populations," was extremely relevant to the special symposium on Amphibian Declines (see below), as Wilbur generally concentrated on characteristics of amphibian populations and problems or concerns in their study. In addition to noting the recently oft-repeated claim that amphibians are very good models for population biology and may well serve as canaries in the coal-mine of environmental decline, he reminded us of the currency that amphibians, especially frogs, carry because "they are cute." Two major themes were to ask what is a population (and how do extinctions and colonizations function in meta-populations—the mostly discrete units found in isolated habitats); and, what are the limits of natural fluctuations in population size?

Contributed paper sessions began Monday afternoon and continued through Thursday, 9 August. These included sessions on Behavior (with 10 papers), Ecology (12), and Evolution (11) Monday; Ecology (12) on Tuesday; Evolution (11), Ecology (12 and 8), and Behavior (9) on Wednesday; and, Conservation Biology (12) and Morphology and Physiology (12) on Thursday. Approximately 250 authors from eight countries (Americas, Australia, and Europe) presented approximately 150 papers. There were 44 posters presented in three sessions, as well as an open meeting with the *Herpetologica* Editors and a *Catalogue of Amphibians and Reptiles* Desktop Publishing Workshop on Thursday afternoon.

SYMPOSIUM

In response to increasing concern among herpetologists about the apparent widespread amphibian decline, and following the widely reported "Irvine, California Workshop" in February, SSAR and HL co-sponsored a special symposium, "Global Crisis in Declining Amphibian Diversity: Analyses of Critical Components," on Tuesday, 7 August 1990, in McAllister Auditorium. Over three dozen participants presented information organized in three broad categories. John W. Wright, of the Los Angeles County Museum of Natural History, organized and moderated the symposium which ran from 8:30 to 5:00 p.m. Wright also described the scope and objectives of the program (generally, to present to a wide audience an overview of the extent of the amphibian decline problem and suggestions for needed action to confirm, understand, and rectify such problems as are acknowledged to actually exist), and presented an audio-tape message from David B. Wake. Wake presented his own impressions of West Coast salamander declines and summarized the findings and recommendations of the Irvine conference (see published accounts: Tree 5(7):203–204; Bull. Ecol. Soc. Amer.; BioScience 40(6):418).

The Symposium was comprised of the following topics and speakers:

REGIONAL ASSESSMENTS OF THE STATUS OF AMPHIBIAN POPULATIONS. *Canada*: Eastern - Lawrence E. Licht; and, Western - Theodore M. Davis. *United States*: Far West - Mark R. Jennings; Rocky Mountains - Steve Corn; Central - James E. Platz; Northeastern - Richard L. Wyman; and, Southeastern and Caribbean - C. Kenneth Dodd, Jr. *Latin America*: Mexico - Oscar Flores-Villela; Nuclear Central America - Jonathan A. Campbell; Costa Rica - George C. Gorman; Panama - Stanley A. Rand; Brazil - Jan Caldwell; and, Peru and Ecuador - William E. Duellman. *Other Regions*: James B. Murphy; and, Summary: Stephen G. Tilley.

POSSIBLE EXPLANATIONS OF DECLINES. Inexplicable Declines: Apparent Taxonomic and Elevation Patterns - Laurie Vitt; Long-Term Studies and Population Fluctuation - Andrew R. Blaustein, Joseph H. K. Pechmann & David E. Scott‹h‹ (SREL), Laurence E. Licht; Amphibians as Bio-indicators of Environmental Degradation - David F. Bradford; and, Possible Contributing or Causative Factors: Global Climate Change, Acid Rain - Richard L. Wyman; UV Radiation - David L. Correll; and, Disease - Elliot Jacobson.

REMEDIAL ACTIONS AND DIRECTIONS FOR THE FUTURE. Inventorying

and Monitoring Standards - Roy W. McDiarmid (Amphibian Handbook), Steve Corn, William E. Duellman, and A. Stanley Rand; Emergency Listing of Threatened and Endangered Species - George Drewry (DES, USFWS); Possible Sources of Funding - James L. Edwards (NSF, via letter); Future Coordination and Communication: Who will maintain the "FROGLOG?" - David B. Wake; Regional Societies and Amphibian Censuses - Steve Hammack and George R. Pisani; Role of Professional Societies - Kraig Adler; and, Role of Governmental Agencies and Other Organizations - Michael J. Bean (Environmental Defense Fund); and, National and International Conservation Efforts - George Rabb.

One thing was made very clear during the Regional *Assessments* — many herpetologists at least think that there is a decline in populations of amphibians, whether local or global in scope. Beyond that, there still seems precious little certainty. As admitted by the presenters, much of the "data" are anecdotal; of course, the vast majority of the remainder are not based upon any long-term evaluations of populations, so the data-base to seriously and adequately address this issue is sparse indeed.

Still it seems risky to ignore the volume of anecdotal and short-term data presented. Many of the populations in apparent decline are known or suspected to be so for the obvious and predictable reasons of habitat loss, destruction, or alteration.

Habitat loss or destruction seems to be most obviously important in Latin America and the southeastern United States. Thus, Campbell reports that Guatemalan rainforest has decreased 85% and a 1990 transect yielded one salamander where 281 individuals of eight species were seen in 1975. Similar, if not quite so severe, reports were made, e.g., for Puerto Rico by Dodd, Brazil by Caldwell, and Colombia by Duellman. Dodd also noted an 85% decrease in southeastern U.S. long-leaf pine habitats. Habitat alteration, through pollution, agriculture, development, or species introductions, appears likely a cause of decline in amphibian populations throughout the hemisphere. Examples include Davis's report on salamander populations in British Columbia, Jennings's on frogs in California, Wyman's on salamanders and frogs in New England, and even Rand's account of changes in frog populations when Barro Colorado Island (Panama) was isolated after canal construction.

The most perplexing and potentially the most ominous declines, however, are those of high altitude populations or those in apparently protected and pristine habitats. Davis noted the virtual extinction of *Rana pipiens* in Alberta and British Columbia. Similarly, several species of ranid frogs were reported in severe decline in the Rockies and Cascades by Jennings and Corn. Gorman reported the disappearance of the golden toad and *Atelopus* at the Monteverde Reserve in Costa Rica and Duellman a dramatic decline of various species in the Andes.

But no area seems immune. The stomach brooding frog appears to be extinct in Australia; and Licht reports cricket frogs nearly gone on Pelee Island in Lake Erie. Platz noted 16 midwestern U.S. species in decline and not all were peripheral species or those in prolonged decline.

As Steve Tilley summarized, "I hear habitat destruction over and over again."

Entering the realm of *Possible Explanations* requires that we entertain both more skepticism and more caution. It is obvious that habitat destruction does not explain all apparent declines. Vitt summarized apparent patterns to the decline and suggested that altitude was prominent as a common thread, especially in the Cascades, Rockies, and Andes, and *Rana* and *Atelopus*, especially, seemed affected, as well as northern, lowland populations of cricket frogs. He further noted that, although the effects of human population pressure, especially deforestation, could not be ignored, one potential factor in the apparent decline may be that herpetologists choose to study populations at peaks of the kinds of long-term fluctuations in size noted by Wilbur in the plenary session. Indeed, Blaustein reported on a population of Rana cascadae that disappeared between 1975 and 1976 and did not reappear until 1988. Pechmann documented different but dramatic fluctuations in species of *Ambystoma* in South Carolina.

Are amphibians appropriate bio-indicators? Bradford presented the rationale for considering amphibians to be a modern, world-wide equivalent of the canary-in-the-mine. Basically, they should be good canaries due to their complex life-cycle, with resultant variable life histories, habitat and trophic requirements, and environmentally-sensitive metamorphs; to the high permeability of skin and egg capsules in various environments; to their generally high fecundities and resultant population fluctuations; and, their often high biomass. What is not yet clearly answered is whether these make amphibians that different from other animals and whether there are documented cases of amphibians disappearing first in environmentally-degraded habitats.

Possible contributing factors are many. Wyman noted that evapotranspiration increases with temperature regardless of rainfall. He also presented evidence that as pH decreases, red-backed salamanders lose sodium and then water. Furthermore, as pH decreases, the number of both individuals and species of salamanders decreases dramatically. Jacobson reported that heavy metals suppress turtles' immune systems; improper nutrition has the same effect.

Obviously, given the uncertainty demonstrated in the preceding two sections, *Remedial Actions* and *Future Directions* may be neither obvious nor direct. Some steps, however, make a great deal of sense whether the apparent decline is real or not. The anecdotal nature of much of the evidence presented earlier in the session emphasizes the need to strengthen our knowledge of the biology and population status of our animals. Roy McDiarmid outlined a program being coordinated by the Herpetology Division at the U.S. National Museum. Perhaps the only thing that could be worse than no data, would be data that could not be compared and interpreted, often due to unknown or incompatible techniques of data collection. The USNM project seeks to establish comparability of sampling protocols and procedures for species inventory and population monitoring work.

Several emergency procedures were also suggested. For species in immediate danger of extinction, emergency listing on the federal endangered species list is possible, although temporary (240 days); some protection is available to proposed species according to Drewry. Solid data on populations are required. McClain demonstrated the limits to emergency captive propagation. Essentially it is a problem of numbers, since a maximum of 15-30 taxa could be so handled by U.S. zoos and aquaria. Strategic, careful planning would be required of the herpetological community if many species are threatened.

Continued efforts to understand and/or ameliorate any threats to amphibian diversity will be required at all possible levels. Pisani, following the analogy of Christmas (and other) bird counts, noted the potential for amateur herpetologists and the regional societies to become involved in supplying important help. Keeping in mind the "Fun Factor," regional groups might be very helpful in species

Two New SSAR Books On Middle East Herpetology:

THE SNAKES OF IRAN

by Mahmoud Latifi

ORIGINALLY published in 1985 in Farsi, the Persian language, Latifi's book is the only comprehensive review of the snakes of Iran. The author is Director of the Department of Herpetology and Antivenom Studies at the Razi Institute in Tehran. This English translation, supervised by Alan E. Leviton and George R. Zug, contains sections on general biology, snake venoms, and snake bite and its medical treatment. There is a key to the 60 species of Iranian snakes, a list by province of their distribution in Iran, and an extensive bibliography. The bulk of the volume (70 pages) consists of a descriptive account and information on size, diet, reproduction, habitat, and distribution for each species. Latifi's classification organizes snakes into eight families: Typhlopidae and Leptotyphlopidae (1 species each), Boidae (6), Colubridae (35), Elapidae (2), Hydrophiidae (5), Viperidae (9), and Crotalidae (1).

The **24 color plates** consist of two relief maps of Iran and 22 plates of snakes (66 individual figures) with species range maps. A new appendix has been added to this edition that contains a supplemental bibliography and a table showing the current terminology for Latifi's names.

Specifications: 164 pages, 24 color plates, 2 maps, 25 figures including 8 photographs in text, 6 x 9 inches (15 x 23 cm), clothbound. To be published March 1991.

Introduction to the HERPETOFAUNA OF IRAQ, KUWAIT AND THE ARABIAN GULF REGION

by Alan E. Leviton, Steven C. Anderson, Sherman A. Minton, and Kraig Adler

THIS HANDBOOK is intended as an introduction to the identification of the amphibians and reptiles of this central part of the Middle East. The region covered extends from the Turkish border south through Iraq, Kuwait, and northern and eastern Saudi Arabia. It also includes the waters of the Arabian (Persian) Gulf and the lowlands bordering it in southwestern Iran and on the Arabian Peninsula, thus also encompassing Bahrain, Qatar, and the United Arab Emirates. The book contains an annotated checklist of 144 species and subspecies, with citation of the original description for each taxon, a brief diagnosis, and a statement of the animals' distribution. There is also an illustrated identification key to all genera, species and subspecies.

The **16 color plates** depict representatives of every genus and most species covered in the book including all species of venomous snakes. Many of these species have never before been illustrated in color. There is a separate chapter on venomous snakes giving detailed descriptions, behavior, and ecology, plus a section on first aid and medical procedures for snake bite, and a table of recommended antivenoms with a list of sources. Also included is an extensive bibliography of Middle East herpetology and an appendix by John E. Simmons on collecting and preservation techniques.

Specifications: About 175 pages, 16 color plates (90 individual photographs), many maps and text figures, 7 x 10 inches (18 x 25 cm), clothbound. To be published June 1991.

TO ORDER

ADDRESS ORDERS to: SSAR Publications Secretary, Dr. Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103, USA. Make checks payable to "SSAR." **Prices include shipping in USA**; overseas postage is additional. Overseas customers must make payment in USA funds or by International Money Order (include extra amount to cover bank charges), or by MasterCard or VISA (in which case account number and expiration date must be provided). For those paying by credit card, a 4% bank charge will be added to your credit card account. If you want information on SSAR membership, mark this box ❑ and return this form with your order.

The Snakes of Iran (ISBN 0-916984-22-2).

- Prepublication price to SSAR members if paid before April 1991 ❑ $17
- Price to Non-members and Institutions and to all others after publication ❑ $22

Herpetofauna of Iraq, Kuwait, and the Arabian Gulf Region (ISBN 0-916984-23-0).

- Prepublication price to SSAR members if paid before June 1991 ❑ $23
- Price to Non-members and Institutions and to all others after publication ❑ $28

SOCIETY · FOR · THE · STUDY · OF · AMPHIBIANS · AND · REPTILES

surveys or even population censuses if a standardized format were available for data collection. The potential exists for worldwide scope. Adler suggested that the professional societies, volunteer-staffed and poor as they are, are not themselves in the position to undertake or fund either the required long-term population studies or the series of careful studies evaluating specific environmental influences on amphibian mortality. They can be facilitators, and as such should produce an international, varied sub-discipline, task force to provide guidance to the herpetological community. Bean noted that, whereas the Endangered Species Act is not likely to be much support in this situation, state natural heritage or non-game wildlife programs receive federal money for conservation needs. Many federal jurisdictions, such as the Forest Service, Department of Defense, and Bureau of Land Management, also have legal mandates to maintain viable populations of vertebrates on their lands.

SOCIAL LIFE

There were additional activities which prevented us from spending the entire five days sitting in darkened lecture halls studying data. An opening social Monday evening included a Cajun band, Cajun dancers, and a Cajun humorist. It was a rousing good time, although the acoustics precluded hearing much of the entertainment and after running out of beer earlier, the social closed before 2300 hours! Tuesday evening involved a barbecue at the Audubon Zoo, where the Herpetology Department showcased an albino and an amelanistic alligator. Later that evening was the annual SSAR Auction, Joe Collins presiding. Fueled by the spirit of supporting the society and the meeting (as well as spirits proper), a lively crowd bid loudly (and also silently on selected items, in a new twist begun this year) for the many items of herpetological interest, including donations of books, equipment, and artwork donated by members and the exhibitors whose displays we perused in the University Center during breaks.

On Wednesday night and Thursday morning, Kraig Adler presented the video show, "Highlights of the First World Herpetological Congress." Wednesday night and Thursday afternoon, Adler, Dave Dennis, and Eric Juterbock presented the multi-media extravaganzas: "Herpetology — Past and Present," by Dennis and Adler, and "Amphibians of the Appalachians" and "Herpetology of the American West," by Dennis and Juterbock, again attended by a large and appreciative audience.

BUSINESS MEETING

The annual Business Meeting of SSAR was called to order by President Brown at 1630 hours on Wednesday, 8 August 1990, in the Stibbs Room of the University Center. He opened the meeting by summarizing the major business he had conducted during the year; three major items were: a membership announcement; formation of a review panel for the Catalogue; and, the special symposium.

Secretary Juterbock briefly summarized Sunday's Board Meeting and noted that those meetings have become incredibly free of controversy (nary a dissenting vote for the second straight year!) and almost short (adjournment before dinner!?!). He announced that the awaited membership drive is still in the offing, after several delays. The SSAR/HL Liaison Committee had by this point met several times. In addition to reports to be summarized, there were several items of note from committees: the Grants-in-Herpetology Committee is looking for a few (or many) good grant proposals in the area of zoo research; the Grants-in-Herpetology program was the recipient of a gift in memory of Cecelia Chang (it will fund a named grant each of next three years); and, the AAZPA Reptile Advisory Group wishes to meet with SSAR in 1991. The Board also agreed to the following: to pay 50% of additional expenses (since donations have already paid for printing and mailing announcements) for the Amphibian Decline Symposium; designate a new family membership category (at a price yet to be determined) which would allow professional spouses to both belong but only receive one set of publications; and, to name an ad hoc representative to the ASIH Public Affairs Committee's joint group working to respond to animal rights issues.

Treasurer Taylor reported that SSAR is financially sound. There were 2156 members as of the end of July 1990. A special projects fund of approximately $14,000 was accumulated and committed to publishing the Gloyd-Conant book (ca. $6000 of that already spent). A 1991 SSAR budget of $117,000 was approved by the Board and should be met; the income from society publications is very important in keeping the society solvent each year. The auction netted approximately $4000; this primarily supports meeting costs.

Sam Sweet, Editor of the *Journal of Herpetology*, stated that the Journal is in "great shape." It is within budget, manuscripts are being received in above normal numbers, and several recently adopted editorial conventions and stable budgets have allowed the lag time from acceptance to publication to be reduced from 17 to 9 months.

Herpetological Review, as reported by George Pisani, is making the transition to desktop publishing. Largely to reduce costs (but also to reduce lag time), about 20% of volume 20 resulted from desktop composition. Volume 21 may end up being 100% desktop. The cadre of keystrokers has been getting the job done, but anyone interested in helping out is certainly welcome to volunteer.

John Wright, who chairs the CAAR Review Panel, noted that the review was requested by the editor and will cover all aspects of Catalogue operations. Editor Villa reported that the 1990 accounts will be published in September. The Catalogue needs authors for new accounts in order to keep publishing on schedule.

Kraig Adler reported on **Facsimile Reprints in Herpetology** and **Contributions to Herpetology**. The 1956 Charles Bogert and Martin del Campo book, "Gila Monster and Its Allies," is planned for release in 1991. **Contributions**, Volume 6, the Gloyd-Conant *Agkistrodon* monograph is due in October. He proposed that SSAR publish the ten Plenary Lectures from FWCH as **Contributions**, Volume 7. A future **Contribution** could be the proceedings of the "Captive Breeding and Conservation of Amphibians and Reptiles" symposium proposed for the 1991 Annual Meeting to honor Roger Conant, a long-time friend of SSAR.

Secretary Juterbock reported for several committees. Six Grants-in-Herpetology of $300 each were awarded in three categories (*Herp Review* 21(3):45).

The winner of the Kennedy Student Award for Volume 23, 1989, of the *Journal of Herpetology* is Gabriel Moreno (Princeton University) for the paper, Behavioral and physiological differentiation between the color morphs of the salamander *Plethodon cinereus*, 23(4):335-341.

Juterbock announced the candidates for terms of office beginning in 1991. President-elect: Victor Hutchison and Edward O. Moll; Secretary: J. Eric Juterbock; Treasurer: Douglas Taylor; Director: Louis Guillette and Rodolfo Ruibal; and, Director (Regional Societies): Harold DeLisle and Stephen

Hammack. There were no nominations from the floor, so it was moved, seconded, and unanimously passed to accept the slate.

Joe Collins begged for sites for meetings in 1993, 1994, or beyond. Although there is the possibility of other meetings taking place outside the U.S. in 1993 and 1994, the SSAR Board decided to have a domestic meeting in those years, regardless.

After a long series of resolutions (see below), Linda Maxson presented a brief preview of the 1991 Annual Meeting at Penn State. She said to expect a "reasonably priced, fun, and intense meeting."

Finally, President Brown presented to President-elect Maxson the official SSAR presidential gavel, which she used to adjourn the meeting at 1745 hrs.

Respectfully submitted,
J. Eric Juterbock
SSAR Secretary

RESOLUTIONS

Decline of Amphibian Populations (Joint)

WHEREAS declines (sometimes drastic) in amphibian populations in many parts of the world have become increasingly apparent to the scientific community within the past several years; and
WHEREAS declining amphibian populations may signal major worldwide environmental degradation and precipitous declines of other life forms; and,
WHEREAS the evidence and opinion presented at the Symposium on Global Crisis in Declining Amphibian Populations indicates that the causes of these declines, though poorly understood, increasingly implicated environmental perturbations and changes produced by human activities; and,
WHEREAS a more thorough understanding of the causes and ramifications of these losses, and of the precipitant general loss of biodiversity worldwide, is in the best interests of humanity, which is obviously affected by environmental degradation; and,
WHEREAS there presently is no uniform system by which to assess critically the extent and causes of these worldwide losses of biodiversity; and,
WHEREAS the rate of this loss of biodiversity is so alarmingly rapid that time is of the essence in establishing such a system;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles (SSAR) and the Herpetologists' League (HL) hereby join other organizations in expressing grave concern over current declines in amphibian populations and biodiversity in general; and, be it
RESOLVED that the SSAR and HL strongly urge the world herpetological community, in particular the members of both amateur and professional herpetological societies, to join in creating effective mechanisms to assess the nature and scope of these declines, with the intent of soon advancing plausible hypotheses for these and marking recommendations to avert further losses; and, be it further
RESOLVED that the SSAR and HL endorse and strongly urge imminent political support and funding of research and monitoring leading to an understanding of the problem of amphibian decline and disappearance, and serving to establish a baseline of knowledge necessary for recommendation of further action that may be warranted.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles and the Herpetologists' League, 8 August 1990 at the jointly sponsored Symposium on Declining Amphibian Diversity.

Turtle Nesting Habitat (Joint)

WHEREAS beaches in Brevard and Indian River Counties, Florida, contain the second densest aggregations of nesting loggerhead sea turtles (*Caretta caretta*) in the world; and,
WHEREAS a large number of green turtles (*Chelonia mydas*) also nest on these beaches; and,
WHEREAS these twenty miles of beach are significant both nationally and internationally for the conservation of these declining species, both of which are protected under provision of the Endangered Species Act of 1973; and,
WHEREAS beachfront development threatens the integrity of these high density nesting beaches; and,
WHEREAS these beaches have been targeted for acquisition as the Archie F. Carr Jr. National Wildlife Refuge in order to protect threatened and endangered nesting sea turtles, their eggs, and hatchlings;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles (SSAR) and the Herpetologists' League (HL), professional scientific societies devoted to the study of amphibians and reptiles, urge the Honorable George Bush, President of the United States, Manuel Lujan, Secretary of the Interior, and members of Congress, particularly those members on the Senate Appropriations Subcommittee, to support the acquisition of the Archie F. Carr Jr. National Wildlife Refuge; and, be it further
RESOLVED that these societies urge the U.S. Fish and Wildlife Service to vigorously use its staff and influence to support immediate acquisition and pursue funding for the Archie F. Carr Jr. National Wildlife Refuge in accordance with its February 1990 policy statement on protection of sea turtles.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles and the Herpetologists' League, 8 August 1990 at the jointly sponsored Symposium on Declining Amphibian Diversity.

Protection of Mexican Sea Turtles (Joint)

WHEREAS Mexico has historically supported the highest species richness and abundance of sea turtles in the western hemisphere, with all but one of the worldwide species nesting on its shores; and,
WHEREAS the sea turtles of the world are an international resource that in the course of their lives travel in and out of sovereign waters of many nations and into international waters; and,
WHEREAS the olive ridley sea turtles are utilized as a sustainable resource for local communities in several Central American nations through a program which protects the long-lived adults and rationally exploits only eggs; and,
WHEREAS Mexico has allowed hundreds of thousands of adult olive ridleys to be harvested during the past two decades, but has recently ended the legal slaughter of 20,000 adults of this species, 99% of which had been identified as gravid females; and ,
WHEREAS a continued harvest of that sort was believed to be unsustainable, based on the fact that three of four major nesting populations of this species in Mexico have already collapsed from commercial over-exploitation; and,
WHEREAS Mexico remains the only nation in the western hemisphere which is not a signatory to the Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES); and,
WHEREAS there has been a call from many Mexican ecological and environmental organizations for Mexico to immediately assent to CITES, without reservations;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles (SSAR) and the Herpetologists' League (HL), professional scientific societies devoted to the study of amphibians and reptiles, applaud the 28 May1990 decree of Mexico's President Salinas de Gortari outlawing the killing of all sea turtles and the harvest of sea turtle eggs; and, be it further

RESOLVED that these societies strongly encourage Mexico's government to vigorously enforce this new decree, to join with all other nations of this region and the 105 countries worldwide as a signatory to the Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES), and to move ahead quickly to provide sustainable economic alternatives for Mexico's turtle fishermen.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles and the Herpetologists' League, 8 August 1990 at the jointly sponsored Symposium on Declining Amphibian Diversity.

Goliath Frog

WHEREAS the Goliath frog (*Conraua goliath*) has unique anatomical, behavioral and physiological attributes and is the largest extant anuran; and,
WHEREAS the Goliath frog is limited to coastal rain forests in the Republic of Cameroon, Equatorial Guinea and Gabon; is further confined within these forests to riverine habitat; is even further limited to areas of waterfalls and rapids; and is always found in low concentrations within these areas; and,
WHEREAS the habitat of the Goliath frog is being rapidly destroyed by clearing of the rain forests and construction of dams on rivers, such as those already built on the Sanaga and planned on the Ntem; and,
WHEREAS the Goliath frog is listed as "vulnerable" in the most recent CITES official lists; and,
WHEREAS a British investor has received Cameroon government permission and international funding to open a Goliath frog farm for frog leg production, which will place further pressures on wild stocks with no scientific basis that such farming will be successful and no economic

evidence that such a venture is appropriate; and,

WHEREAS recent major media coverage in the United States of the use of this species in "frog jumping contests" and coverage of the importation of the animals have resulted in increased demand by private collectors and others; and,

WHEREAS live Goliath frogs are being advertised by animal dealers at prices ranging from about US$1500 to US$3000 each, and such value is an indication of their rarity and of the economic forces driving further exploitation; and,

WHEREAS this species is subject particularly to stress of capture, handling, shipping, and confinement with resultant high mortality levels, and has not been bred successfully in captivity;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles (SSAR) assembled at its annual meeting for 1990 in New Orleans, Louisiana, USA, respectfully urges all parties with appropriate regulatory jurisdiction over collection, trade, and conservation management take necessary actions to insure the survival of *Conraua goliath* in the wild; and, be it further

RESOLVED that copies of this resolution be sent to: the appropriate agencies within the governments of the Republic of Cameroon, Equatorial Guinea and Gabon; the World Wildlife Fund; TRAFFIC (USA); World Conservation Monitoring Centre (Cambridge, United Kingdom): IUCN (AFHERP Group), Trade Specialist Group); CITES (Secretariat, Lausanne); ISSCA Conservation Committee; U.S. Fish and Wildlife Service (Office of Management Authority); California Fish and Game Commission; and to any other organizations or agencies identified as having interest in the conservation of this species.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 8 August 1990 at its Annual Meeting.

Honoring Outgoing SSAR Officers and Editors

WHEREAS the following individuals have given freely of their time, insight, and knowledge to the Society for the Study of Amphibians and Reptiles in this past year in advancing its goals and furthering its development as an international society; and,

WHEREAS said Society is greatly indebted to these persons for their continual efforts in its behalf; and,

WHEREAS certain of these persons have, over the years, freely gives so extensively of themselves to SSAR that to enumerate all their individual contributions here would have the audience yelling for my head;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles offers its most sincere thanks to the following persons who have served in these capacities:

HENRI SEIBERT - Immediate Past-president
LYNNE D. HOUCK - Director
JAMES P. BOGART - Director
JIM VIAL - Managing Editor, Journal of Herpetology
CARL GANS - Chair, Nominating Committee

BE IT FURTHER RESOLVED that the SSAR urges these persons not to ride off into the sunset, but rather to, with or without official titles, continue to be available as resources to help those who follow better guide the Society

Adopted by the Society for the Study of Amphibians and Reptiles, 8 August 1990 at its Annual Business Meeting.

Thanking The Local Committee (Joint)

WHEREAS nearly 500 herpetologists trekked to the sunny south, braving the threats of excessive shrimp consumption, the French Quarter, untold encounters with crabs (marine ones), an abundance of drinking establishments, and the annual pleadings of the auctioneer; and,

WHEREAS Harold Dundee, Ernie Liner, Richard Seigel, and their numerous colleagues and assistants at Tulane University and the Audubon Zoo in a state which has nearly as many herpetologists as it has species of herps, performed a great service for the SSAR and the Herpetologists' League by agreeing to undertake the arduous task of housing a meeting of this size; and,

WHEREAS this meeting maintains a tradition of the joint SSAR and HL annual meeting providing an outstanding forum for the dissemination of ideas and information; and,

WHEREAS Tulane University has generously allowed the societies to use the conference facilities without charge; and,

WHEREAS all participants have had a fine time in a herpetologically and socially diverse setting;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles and the Herpetologists' League offer their most sincere thanks to these persons who worked so hard to make this meeting a success; and, be it further

RESOLVED that these societies extend a special note of appreciation to our official host, the Biology Department of Tulane University, recently reorganized in part into the Department of Ecology, Evolution, and Organismal Biology, for inviting us to the Tulane Campus this year.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles and the Herpetologists' League, 8 August 1990 at their joint Annual Meeting.

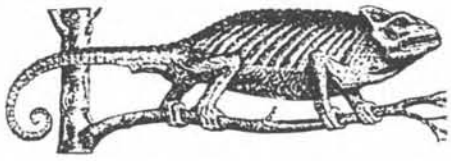
COMMENTS ABOUT THE AMPHIBIAN DECLINE SYMPOSIUM

This writer, for one, drew the following conclusions after seven hours of presentations. It is very hard to be optimistic! Although there are *no solid data to support a hypothesis of wide-spread decline* of amphibian populations, there are also *no solid data to support a hypothesis of wide-spread stability*, either. Furthermore, several points are troubling.

In the first place, we have identified numerous reasons to *expect* declines. If amphibian populations are stable or only naturally fluctuating, in spite of the myriad assaults on their habitats, especially those that are destroyed outright, they are certainly different than many other organisms that are more visible if not better known. Most depressing in this regard is that it seems very unlikely that anything short of stopping population growth, improving the world economy by orders of magnitude, and converting the world citizenry to environmentalism, will significantly change these expectations.

SSAR Regional Societies Amphibian Monitoring Workshop; March 1991; Fort Collins, CO

Basic, ongoing amphibian population monitoring is necessary to assess changes in their status. Regional societies have the resources to make real contributions to scientific knowledge of the status of local amphibian populations. The SSAR Regional Societies Liaison Committee has developed a model database for this effort, and at the workshop will illustrate how your society can use this both to add fun to field trips and to collect/share data of importance to amphibian conservation efforts. The workshop is being held as part of the symposium *Biodiversity of the Rocky Mts.* (Colorado State Univ.). **For details and registration info, contact Steve Hammack (SSAR Regional Soc. Comm. Chair), Fort Worth Zoo, 2727 Zoological Park Drive, Fort Worth, TX 76110.**



Second, accepting that the data are incomplete, anecdotal, sometimes inconsistent, and almost never long-term, why do so many field herpetologists *think* that they are witnessing declines in the species they are most familiar with? It seems to me that if our intuition were so often wrong, herpetology would not be advancing as it is. Therefore, it seems to me the bottom line is obvious: *we need survey data*; and we need them yesterday!

As herpetologists, we owe it to our animals to know more about their geographic distribution, habitat utilization, species assemblages, and population sizes. As conservation biology edges closer to the triage stage, we are going to have to be able to make such decisions about local habitats as what species are there, in what numbers, and how important is that association to the health of the meta-population. Until we can do that, we will never be able to make the best emergency management decisions. In reality, the uproar over the possibility of a global amphibian decline is the canary, and our data bases the mine. If the canary ain't dead, it sure is breathing irregularly! Let us all move forward in building data bases adequate to these questions. Is it the worst-case or best-case scenario that we will collect the data and find that amphibians have not yet declined?

J. Eric Juterbock ●

ADVERTISERS WANTED

Herpetological Review always is interested in alerting SSAR members to new books, equipment, or supply sources which are of use to the herpetological community. Many of our advertisers have been with us for years because the responses to their ads in *HR* were so positive. If you know of any distributors, publishers, or manufacturers who might benefit from an ad in *HR*, please let them know about us - or let us know about them so we can invite them to advertise in our publication. ●

SYMPOSIUM AND VOLUME TO HONOR ROGER CONANT

Symposium. During the 1991 joint SSAR-HL meeting at Pennsylvania State University (6-10 August), a special two-day symposium, entitled "Captive Management and Conservation of Amphibians and Reptiles" will be held. This will include 45 of the leading international authorities and is being organized by James B. Murphy (Dallas Zoo) and Joseph T. Collins (University of Kansas). The results will be published as a book.

This event will be dedicated to Roger Conant, who will celebrate his 82nd birthday in May. Dr. Conant's *Field Guide*, the most widely-used herpetological book of all time, has been extremely influential in the development of North American herpetology and the third edition will be published next spring.

Appreciation Volume. As part of the ceremony to honor Dr. Conant, a bound volume of letters from friends and colleagues will be presented to him. Ordinarily, these letters are solicited privately, but since Roger Conant's life's work has influenced so many persons far and wide—both professionals and amateurs alike—we issue this public solicitation so that all can contribute.

If you wish to include a letter in the volume, stating your own appreciation, simply write it on a piece of paper measuring 8 1/2 by 11 inches, leaving a margin for binding. Mail these unfolded and flat to: Dr. Joseph C. Mitchell, Department of Biology, University of Richmond, Richmond, Virginia 23173.

The deadline for receipt of letters is: 1 June 1991.

Contributors to Student Travel Fund

Last year, the Student Travel Fund Committee directed financial support for travel to eight doctoral students attending the First World Congress of Herpetology in Canterbury, England. These students were: Elisabeth Arevalo (Brigham Young University), Joseph Bernardo (Duke University), Ann Burke (Harvard University), Richard Cloutier (University of Kansas), Reginald Cocroft (University of Texas), Linda Ford (University of Kansas), Raphael O. De Sa (University of Texas), and Brent Palmer (University of Florida).

On behalf of these students, the Committee extends its sincere thanks to the following individuals for significant financial donations: Ronn Altig, Edmund D. Brodie, Jr., James R. Dixon, William E. Duellman, Victor Hutchison, David L. Jameson, Robert R. Miller, Sam Sweet, Linda Trueb, Marvalee Wake, and David Wake.

The Committee also thanks the following institutions, organizations, and commercial concerns for their generous support: Alan R. Liss, Inc.; American Society of Ichthyologists and Herpetologists: British Airways; Facts on File Publications; Donald E. Hahn; The Herpetologists' League; Holbrook Travel, Inc.; Milwaukee Public Museum; Museum of Comparative Zoology, Harvard University; Princeton University Press; Smithsonian Institution Press; Society for the Study of Amphibians and Reptiles; T. F. H. Publications, Inc.; University of California Press; University Presses of Florida; University of Pittsburgh Press; W. H. Freeman and Company; and Wildlife Materials, Inc.

David Cundall
Chair, HL, ASIH, SSAR
Student Travel Fund Committee ●

NEWSNOTES

TARANTULA SLIDES WANTED

Dr. Robert Raven, curator at the Queensland Museum, and Rick West, research associate at the Royal British

Columbia Museum, are gathering specimens, photoslides, and data on theraphosid spiders (tarantulas) for a planned book. Although tarantulas are not herps, it is fair to say that herps, herpers, and tarantulas often share the same microhabitat.

The assistance of SSAR members, and friends, is requested. Please send us photoslides and/or data on both Old World and New World tarantulas to aid our project. Photo credits would be given if any photoslides are used, and species names would be provided if determined from the photoslide.

Please forward slides or data to: Dr. Rick C. West, Toral B.C. Museum, 4034 Glanford Avenue, Victoria, B.C., Canada V8Z 3Z6. (604) 479-1533. ●

INFORMATION REQUEST

Information is currently being collected for a North American Regional Studbook on the Chinese crocodile lizard, *Shinisaurus crocodilurus*. If you have had specimens of this taxon in your collection at any time and would like your information published in the studbook, please contact Andy Snider, Reptile Department, Audubon Park and Zoological Gardens, P.O. Box 4327, New Orleans, LA 70178, USA, or call (504) 861-2537. ●

VOUCHER SPECIMENS SOUGHT BY USFWS

The U.S. Fish and Wildlife Service's Forensic Laboratory in Ashland, Oregon, USA, is in need of assistance. Colubrid snakes from Asia, along with crocodilians, sea turtles, boas, pythons, and varanid, iguanid, and tupinambid lizards from around the world are falling prey to the fashion industry in the form of tanned leather. The mission of the Forensic Laboratory is to provide law enforcement agents with accurate and court-defensible species-level identifications of such products.

I am calling upon the general herpetological community to assist in building our reference collection containing voucher specimens of all commercially valuable taxa. If you have materials (preserved specimens, frozen carcasses, raw or tanned hides, etc.) that we might use, please contact: Stephen D. Busack, National Fish and Wildlife Forensics Laboratory, 1490 East Main Street, Ashland, OR 97520, USA. Shipping will be paid for, and a fair market value for any donations will be determined so that donations can be deducted from Federal taxes. ●

AMNH VOLUNTEERS

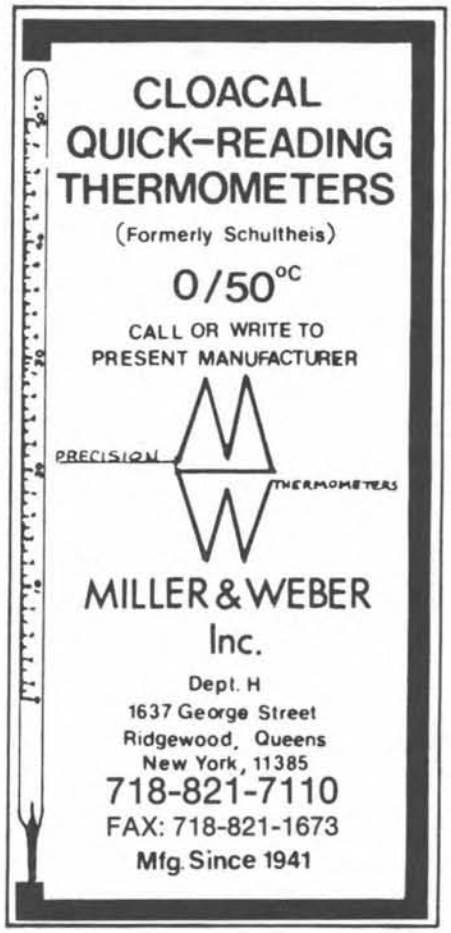
Approximately 20 volunteer positions are open in 1991 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for four hours per day of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students - the latter may pursue their own research projects. *Faculty knowing of promising students should alert them to this opportunity* for professional experience toward, development of, and evaluation of, their career goals.

Volunteers are needed between 15 March and November. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March through May) should submit forms by 15 February., summer volunteers (June-August) by 1 April, and fall volunteers (September-November) may apply any time.

For application forms, write: Resident Director, Southwestern Research Station of the American Museum of Natural History, Portal, AZ 85632, USA. (602) 558-2396. ●

Clemmys PROTECTION RESOLUTION



WHEREAS, it has become increasingly evident that the populations of eastern *Clemmys (C. guttata, C. insculpta, C. muhlenbergii)* face serious survival threats throughout most if not all of their ranges; and

WHEREAS it has become clear that collection from wild populations of *Clemmys* has substantially contributed to these threats; and

WHEREAS, the majority of these populations are protected by law, and thus many wild-caught specimens offered for sale are in fact illegal:

THEREFORE, BE IT RESOLVED, that all collection from wild populations of *Clemmys* be stopped; that purchase of *Clemmys* be limited solely to specimens with clear proof of captive-bred status; and that those who presently maintain *Clemmys* increase their efforts to reproduce them, thereby increasing the availability of captive-bred animals.

Submitted by: AAZPA Turtle and Tortoise Advisory Group Coordinators, Brett Stearns, Chairman, Dave Collins, Dennis Herman, Bern Tryon. ●

SEA TURTLE TAG CENTER OF THE PACIFIC

The Sea Turtle Tag Center of the Pacific is a cooperative program to make available tags, tag applicators, and technical assistance in the tagging of sea turtles for research purposes to government and other qualified organizations in the Pacific islands region of Polynesia, Micronesia, and Melanesia. The program

is jointly conducted by the Southwest Fisheries Center Honolulu Laboratory of the National Marine Fisheries Service, NOAA, and the University of Hawaii's Hawaii Institute of Marine Biology (HIMB). The program is designed in particular to aid those locations where small to moderate numbers of tags (i.e., 100-500) are needed, and local authorities or organizations might not otherwise order them from the manufacturer.

The Inconel tags are self-piercing, self-locking, and simple to use when applied with a special plier-like applicator to the trailing edge of a turtle's front flippers. All tags are imprinted consecutively with a letter-number combination to permanently identify individual turtles. The following inscription appears on each tag:

Write HIMB
University
Hawaii 96744

Persons who report the resighting of a tagged turtle to this address are sent a T-shirt bearing a sea turtle logo. The resighting information that is received is relayed to the tagging organization.

For more information about the availability of tags from the Sea Turtle Tag Center of the Pacific, write to: G.H. Balazs, Southwest Fisheries Center Honolulu Laboratory, National Marine Fisheries Service, 2570 Dole Street, Honolulu, HI 96822-2396. (FAX 808-942-2062) ●

AMPHIBIAN LARVAL BIOLOGY

A course on amphibian larval biology is being offered at the Highlands Biological Station, Highlands, North Carolina, 3-14 June 1991. It will be taught by Dr. Richard Wassersug of Dalhousie University with the assistance of several guest instructors. Credit for the course is available through either Western Carolina University or the University of North Carolina at Chapel Hill. For forther information and application forms, contact: Highlands Biological Station, PO Box 580, Highlands, NC 28741, USA. (704) 526-2692.●

THE ROGER CONANT RESEARCH FELLOWSHIP

The Roger Conant Research Fellowship was established in 1990 to honor the scientific contributions of Roger Conant, the Toledo Zoological Society's first Curator and Research Scientist. It is designed as a vehicle to promote career development in zoo research and management in outstanding undergraduate and graduate students.

Tenure of Fellowship: A flexible two-month period falling between 1 May and 31 August each year.
Stipend: $1,500 for the period of the fellowship. Lodging adjacent to Zoo grounds will be provided by the Society.

Eligibility: Junior, senior, or graduate students from an accredited four-year university majoring in animal husbandry, biology, wildlife management, veterinary science, zoology, or allied field.

Types of Projects: Emphasis will be on student participation in projects developed by Toledo Zoo staff and carried out in the animal departments of the Department of Conservation and Research. Exceptions for student generated research will be made for applicants with demonstrated research potential. All research will be directed or supervised by a Departmental Curator, Research Scientist, or Staff Veterinarian.

Mode of Selection: Selection of Conant Fellows will be made on the basis of merit. Grades, letters of recommendation, and relevant experience will all be considered in making the final selection.

Application: Application materials may be obtained from: Dr. Peter J. Tolson, Conservation Biologist/Research Coordinator, Toledo Zoological Society, P.O. Box 4010, Toledo, OH 43609, USA.

The closing date for applications is 1 April of each year. Awards will be made by 1 May. Two letters of recommendation from persons familiar with the collegiate performance or research potential of the applicant, including a letter from the student's most recent advisor or major professor, are required. A copy of the student's most recent college transcript is also required. No application will be processed until all supplementary materials are received. ●

AAZPA CHELONIAN ADVISORY GROUP FORMED

The Wildlife Conservation and Management Committee of the American Association of Zoological Parks and Aquariums (AAZPA) has approved the formation of a Chelonian Advisory Committee.

The group, initially convened as a Special Interest Group, commenced its activities at a Herpetology Species Survival Plan meeting held in Gainesville, Florida in April 1990.
At that meeting, 21 people, representing many zoos throughout the country, agreed to serve as the group's initial members. Of these, Dave Collins (Burnet Park Zoo, Syracuse, NY), Dennis Herman (Zoo Atlanta, Atlanta, GA), Brett Stearns (Institute for Herpetological Research, Stanford, CA), and Bern Tryon (Knoxville Zoo, Knoxville, TN) were selected as Group Coordinators.

The group's purposes include coordinating with and supporting other on-going chelonian conservation projects, such as the IUCN's Tortoise and Freshwater Turtle Action Plan. One of the group's first projects will be to enlist the cooperation of American zoos in streamlining their chelonian collections by pairing up breedable animals and in making more space available for chelonians most in need of captive management and breeding programs.

The coordinators encourage input from the private sector, as well as from academic and field researchers who are actively involved in conservation and management programs for chelonians.

Bern W. Tryon
Department of Herpetology

MEETINGS

SECOND WORLD CONGRESS OF HERPETOLOGY

The Second World Congress of Herpetology will be held at the University of Adelaide, Adelaide, South Australia, 29 December 1993 - 5 January 1994. This international congress is the second of a series that started in 1989 in Canterbury. This meeting will enable all persons interested in herpetology to meet and exchange information to promote the advance of

knowledge and the conservation of the world's amphibians and reptiles. The congress will consist of topical symposia, plenary speakers, poster sessions, workshops, displays, excursions, and meetings of ancillary groups, and will offer visitors the opportunity to get acquainted with the unique and diverse Australian herpetofauna. Subjects and moderators will be announced well in advance so that potential participants can volunteer. The meeting will be open to all persons. Registration will begin 1 January 1992.

Further announcements about registration, travelling arrangements, accommodation, and program will be made in herpetological journals as soon as available. For further details and mail listing, write: Dr. M.J. Tyler, The University of Adelaide, Department of Zoology, Box 498, GPO, Adelaide, South Australia 5001, Australia.

Sponsoring organizations and individuals are welcome. For further details, write: Dr. R.L. Carroll, Treasurer WCH, Department of Biology, McGill University, 1205 Docteur Penfield Avenue, Montreal, PQ, Canada H3A 1B1. ●

1991 ASC ANNUAL MEETING

The Association of Systematics Collections will hold its 1991 annual meeting at Texas A &M University, College Station, Texas on 16-18 May 1991. The meeting will feature a workshop on "Biodiversity and Collections." Speakers from the U.S., Canada, and several Latin American countries will discuss the role of collections in biodiversity studies, international collaboration in biodiversity studies and collection development, and the status and needs of collections in developing countries. There will also be a workshop on Collections Policy issues. Participants are welcome. For further information, contact ASC at 730 11th Street NW, Second Floor, Washington, D.C. 20001. (202) 347-2850. ●

REPTILIAN CHEMICAL SENSES

A Conference on Reptilian Chemical Senses will be held 15-16 June 1991 at the Penn Towers Hotel, Philadelphia, Pennsylvania, just prior to the Chemical Signals in Vertebrates meeting scheduled for 16-22 June at the same location. For information concerning the conference, contact Dr. Mimi Halpern, Department of Anatomy and Cell Biology, Box 5, SUNY Health Science Center at Brooklyn, Brooklyn, NY 11203, USA. (718) 270-2958. FAX: (718) 270-3378. ●

BHS MEETINGS - 1991

Meetings of the British Herpetological Society are held in the Lecture Theatre of the Linnean Society of London, Burlington House, Piccadilly, London W1, generally starting at 7.00 pm and ending at 9.00 pm. SSAR members and herpetologists from other countries are most welcome.

February 14: Dr Wolfgang Wuster (Department of Zoology, University of Aberdeen): Cobras and other herps in Southeast Asia.

March 23: A.G.M. (separate agenda). A special Saturday all-day event to be held at Birkbeck College, London (Malet Street, London WC1).

April 17: Dr Robert Bustard (Isle of Man): Sea Turtles on Australia's Great Barrier Reef.

May 23: Dr Robert Oldham (Department of Biology, Leicester Polytechnic): Nigerian Amphibia (postponed from 1990).

June 18: Mr Geoff Clarke (Bere Regis, Dorset): Amphibia and Reptilia Worldwide - Their Care and Breeding.

September: Date to be announced. Care and Breeding of Amphibians and Reptiles: An Open Meeting. Contributions from members; live animal & photographic displays; sales and exchanges; commercial displays of books & vivarium equipment. 2.00 to 5.30 pm. Lecture Theatre of the Soo Studies Centre, Zoological Society of London, Prince Albert Road, London NW1.

October 10: Dr Michael Lambert (BHS Chairman): Some African Herpetofauna and the Impact of Tsetse Control Insecticides on Lizards in Zimbabwe.

November 20: Mr Mark Day (Gambian Dwarf Crocodile Rescue Project, University of Bristol): Herpetofaunal Wading Through West Africa.

For further details, membership, information on publications and subscriptions to the Herpetological Journal and quarterly BHS Bulletin, contact: BHS, c/o Zoological Society of London, Regent's Park, London NW1 4RY, UK.

Michael R.K. Lambert Chairman, British Herpetological Society ●

HIGHLANDS CONFERENCE ON PLETHODONTID SALAMANDERS

The Highlands Conference on Plethodontid Salamanders will be held in early June 1992 at the Highlands Biological Station in Highlands, North Carolina. This meeting will follow the tradition of the first (1972) and second (1982) conferences in exploring new directions in plethodontid research. The conference features invited papers, an evening poster session, and a symposium. All interested parties are encouraged to participate.

Future announcements concerning conference dates, a call for papers, and registration information will be sent only to those on our mailing list. To receive these announcements, send your name, address, and phone number to: Dr. Robert Jaeger, Department of Biology, University of Southwestern Louisiana, Lafayette, LA 70504-2451, USA. (318) 231-5235. FAX (318) 231-5834. ●

LEGISLATIVE ALERT

This column is produced by the SSAR Conservation Committee to alert members of the herpetological community to recent and proposed regulatory changes involving amphibians and reptiles. We encourage SSAR members to notify us of any significant changes in state, national, or international conservation laws as they relate to these animals. For further details about any of the following, or to report additional changes, please contact Kurt A. Buhlmann, SSAR Conservation Committee, c/o Division of Natural Heritage, Virginia Department of Conservation and Recreation, 203 Governor Street, Suite 402, Richmond, VA 23219, USA.

The following final and/or proposed listings and regulations have been announced by governmental regulatory agencies. Pertinent *Federal Register* (FR) citations are given for U.S. notices.

U.S.: *Graptemys flavimaculata* (yellow-blotched map turtle); proposed as Threatened [FR 55(133): 28570-28573, 8/11/90]

This basking turtle is restricted to the Pascagoula River system in Mississippi, including the Leaf and Chickasawhat Rivers and other tributaries. It is threatened by habitat modification, wanton shooting, collecting, water quality degradation, and nest predation.

MEXICO: The government of Mexico has announced that it is prohibiting the take of sea turtles in its waters and the destruction of turtle nests. Accompanying this decision, the government is: initiating a program to study the magnitude of incidental take of sea turtles during fisheries activities; extending offshore and beach refuge zones; increasing scientific studies aimed at protection and conservation of sea turtles; and registering all existing stockpiles of sea turtle products (Endangered Species Technical Bulletin, Vol XV, No. 7, July 1990).

Florida: *Gopherus polyphemus* (gopher tortoise); incidental take, draft rule

In Florida, where gopher tortoises are listed as a Species of Special Concern, the combined forces of urbanization, residential development, agriculture, forestry, and mining are destroying hundreds of thousands of acres of tortoise habitat annually. Although the state extracts some mitigation for habitat lost to the largest developments, 95% of the loss is unmitigated. The Florida Game and Fresh Water Fish Commission is now drafting rules that would require some habitat mitigation or preservation for tortoise burrows that are destroyed during developmental and agricultural activities (i.e. incidental take). The draft rule will then be presented to the Commission for consideration, perhaps as early as November 1990. As expected, strong resistance to such a rule is being exerted by developmental and agricultural interests. For additional information, contact; Col. Robert M. Brantly, Executive Director, Florida Game and Fresh Water Fish Commission, 620 S. Meridian Street, Tallahassee, FL 32301, USA.

FEATURES

A CONGENITAL LUNG DISORDER IN A JUVENILE HEAD-STARTED KEMP'S RIDLEY SEA TURTLE (*Lepidochelys kempi*)

Since 1978, the National Marine Fisheries Service (NMFS), Southeast Fisheries Center, Galveston Laboratory, Galveston, TX, has been involved in an effort to save from extinction the most endangered species of sea turtle, Kemp's ridley (*Lepidochelys kempi*). This conservation program is a cooperative venture among Mexico's Instituto Nacional de la Pesca, the U.S. Fish and Wildlife Service, the National Park Service, the Texas Parks and Wildlife Department, and the NMFS. The NMFS husbandry portion of the program is referred to as head starting.

Diseases encountered in the husbandry of the Kemp's ridley sea turtle have been documented by Clary and Leong (1984) and Leong et al. (1989). Leong et al. (1989) reported that some apparently healthy Kemp's ridleys die of no explainable cause during head starting. We report herein the death and necropsy of an outwardly healthy Kemp's ridley with congenital lung defects.

The turtle in question showed no external signs of illness or disease before its death. It apparently was feeding well and its growth appeared normal as compared to others from the same clutch (Table 1). At the time of death, the turtle was 4-1/2 months old, had a mass of 110.5 g, and had a straight-line carapace length of 8.6 cm and a straight-line carapace width of 7.9 cm. Though the turtle was examined for external marks, lesions, or deformaties, none was found.

The necropsy proceeded as recommended by Rainey (1981) and Wolke and George (1981). The turtle was placed on its back and the plastron removed by cutting along its margin through the skin and between the marginal and inframarginal scutes. The plastron was then pulled up, the pectoral and pelvic muscles severed, and the plastron removed. Initial examination showed that all major organs were present and appeared to be in the proper position. The lungs, however, were much smaller than expected for a Kemp's ridley sea turtle of this size. Whereas the lungs of a turtle of this size and age normally cover two-thirds of the dorsal body cavity, this turtle's lungs, although normal in length, did not extend more than a few mm beyond the spinal column. The right lung was smaller than the left, and on first observation was thought to be absent. The lungs, although vestigial, were pink in color and contained no fluid.

Kemp's ridley sea turtle hatchlings received for head starting have exhibited a variety of externally manifested congenital birth defects (Leong et al. 1989). It would be expected that corresponding internal defects would be present in such turtles as well. However, the congenital lung problem described herein occurred in a turtle with no outward signs of abnormalities. It seems likely that a reduced lung capacity could supply oxygen to a turtle's tissues only up to a certain size. Once the mass of such a turtle increased beyond this point, pulmonary dysfunction could occur and the turtle would die. We believe that the death in this case was related to the congenital lung defects.

Researchers performing necropsies on apparently healthy specimens of Kemp's ridleys that die in captivity should look closely for internal evidence of abnormalities.

OBSERVATIONS ON THE LIZARD *Shinisaurus crocodilurus* IN CAPTIVITY

The Chinese crocodile lizard (*Shinisaurus crocodilurus* Ahl,1930) has been considered rare and enigmatic since its first description, with few specimens reaching western museums or zoos until 1984 (Wilke 1985). Most of our knowledge of this lizard was based on field notes of the original collector (Fan 1931) and on anatomical studies on very few specimens (cited in Hu et al. 1984). The taxonomic status of this lizard is uncertain with placement either in Xenosauridae (Mc-Dowell and Bogert 1954) or in Shinisauridae (Ahl 1930; Hu et al. 1984; Wu and Huang 1986).

Recently, Shen and Li (1982) described feeding, reproduction, and other behavior of this species in the wild. Wilke (1985) reported on captive specimens, especially housing conditions and feeding problems. Sprackland (1989) provided many observations on feeding, sexual dimorphism, behavior, and captive births. The present note provides additional observations on the Chi-nese crocodile lizard.

A female *Shinisaurus* (15 cm SVL) was purchased from a local petshop 25 July 1989. It was maintained in a commercial 55 gallon glass aquarium (91 x 43 x 30 cm). The tank was propped 2 cm from the horizontal at one end, such that tap water (allowed to stand at room temperature for 2-5 days) formed a pool (1-2 l) ca. 3 cm at the deep end. The dry floor area was ca.

Computerize Your Field Notes and Collections

GECKO is a computer program for managing field notes and collections.

GECKO will allow you to:
Record genus, species, subspecies, number, locality, county, state, collector or observer, collection number and comments. Family, order and class are entered automatically.
Extract data for viewing, editing or printing by any combination of the above, e.g. iguanid lizard localities for Inyo Co, CA or all herps seen in Texas from June through August.
List data by order of entry, by date or phylogenetically.
Copy selected records to files for use with spreadsheets, word processors or data base programs.
Count number of species for all or part of the data base, e.g. number of species for 1988 or number of species of *Hyla*.

GECKO is very powerful, yet uses simple screen menus. It incorporates a master species list and is sold with your choice of the U.S. and Canadian list of herps, birds or mammals. Other species lists can be purchased separately and merged into a comprehensive list of terrestrial vertebrates. Lists can be easily edited to accommodate taxonomic changes or new species.
GECKO runs on IBM PCs and compatibles with 320K RAM and DOS 2.0 or later. $75 + $3 shipping. California residents add 6% tax. Please specify species list to be included. Additional lists are $25 each. Similar programs which use common names are available for all terrestrial vertebrates.

Sandpiper Software 153 Michele Circle, Novato, CA 94947

30 x 25 cm. A flat rock 14 x 16 cm was placed at the water-land interface. A smooth tree branch 60 x 2 cm was placed between the rock and the top of the tank. A cardboard hide box (20 x 20 x 15 cm) with a single opening was placed on the dry floor area, but was removed after several weeks when it was obviously not being used.

The tank was covered with wire screening. Air temperature ranged from 18 to 24° C, always cooler at night. Usually a 10 h light/14 h dark cycle was maintained in the room (standard fluorescent tubes). Vita-Lite illumination (Dura-Lite 40W) directly atop the tank was provided 3-8 h daily, averaging 5 times a week.

Feeding. The *Shinisaurus* fed well after an adjustment period of five days, during which time no food was offered. Food was offered during the day, since the lizard was not active at night. Crickets, sometimes dusted with bone meal powder, were accepted. Crickets tended to evade the lizard unless one or both jumping legs were removed. Immobile crickets were not attacked unless they had been tracked. Crickets were more readily caught on land, and the lizard would leave the water to chase them. Crickets swimming in the water were eaten, though the *Shinisaurus* had difficulty seizing the crickets, often missing or failing to grip them properly. Crickets taken on land were consumed there. Prey capture was done with the jaws alone, with no tongue protrusion. Use of the forelimbs in manipulating or dismembering prey was never observed.

Earthworms were also avidly eaten, both on land and with some difficulty in water. Swimming goldfish and bait minnows (2-3 cm) were ignored. When the fish were placed on the land surface, however, the lizard immediately left the water and readily devoured them. About six months after the first trials, goldfish (1-2 cm) were again offered. This time the lizard attempted to seize the fish but did not succeed. It attempted to catch the fish by lunging at them from above rather than approaching them at or below the water surface, although the water was deep enough for submergence. These observations do not agree with statements that this species feeds on tadpoles and fish in nature (Fan 1931). Shen and Li (1982) were told by natives that *Shinisaurus* fed on tadpoles and grasshoppers, but the only stomach examined by them contained other insects and grass seeds. Sprackland (1989) reported that his specimens ignored live guppies. Newborn laboratory mice were eagerly taken on land. The *Shinisaurus* would seize them and then retreat into the water, where it would consume the mice while standing in shallow (ca. 1-2 cm) water.

Seedless red grapes and strawberries were also accepted. Small pieces were placed on the rock, and the lizard would approach the rock and seize them. Some larger pieces were shaken, brushed against the rock, and torn into smaller pieces which were then swallowed. Pieces of these fruits on the end of a toothpick were also taken after a few attempts; pieces of banana offered in the same way were not. This is apparently the first record of *Shinisaurus* feeding on fruit. Canned dog food was not accepted. Defecation usually occurred in the water, infrequently on land.

Climbing behavior. A branch was always present in the cage, yet the lizard did not climb it every night as lizards of this species may do in the wild (Shen and Li 1982). When on the branch, the lizard laid with its limbs slightly wrapped around the branch, so that the feet approached each other under it. The tail was held off the branch to one side, or resting along its top, but would not be wrapped around it.

The lizard was once observed climbing onto the branch. It reached for the branch with its two forelimbs while standing in water. It pulled itself up using both forelimbs, then walked to near the top of the branch. While walking, the lizard held its tail against the side of the branch (and not loosely dangling) implying a balance role for the tail. Such "pressing" of the tail against the side of the branch was also observed when the lizard was at rest. No fully prehensile use was observed.

Despite the overall lethargic behavior of the lizard, it was capable of notable climbing activity. On one occasion, the lizard was observed clinging upside down to the screen cover of the tank ca. 70 cm from where the branch contacted the screen. The lizard hung by only two claws on each foot. The limbs extended laterally from the trunk and no other part of the body touched the screen. The tail extended horizontally from the body for about half its length, then arched gradually towards the floor. The lizard was observed in this position for about an hour. When observation resumed two hours later, the lizard had descended (perhaps fallen) to the floor of the tank.

Reproduction. This lizard was isolated from other *Shinisaurus* from the date of acquisition; the amount of previous intraspecific contact is unknown. On 15 March 1990, a dead, well formed crocodile lizard (55 mm SVL, 62 mm tail length) was discovered in the water. It was wrapped in fetal membranes, and was attached to its yolk sac. Its size agrees with those of eight live born young observed by Huang (1983) (total length 121-131 mm). However, the young observed by Huang all lacked yolk sacs at birth, as did the advanced embryos found within dissected females. Whether the present neonate was stillborn or died after birth is unknown. Huang reports (1983) that neonates may or may not be covered with membranes at birth, and if not, the young may walk directly out of the mother. It is also unknown if birth in this case occurred in water, although Huang (1983) reports this to be the case at least in captivity. Gestation in the present instance took a minimum of 234 days, similar to that reported by Shen and Li (1982), and Huang (1983).

Coloration and Ecdysis. Ahl (1930) reported on the basis of one male and female (fluid preserved), that the male was overall more reddish than the female, which was overall grayish. The underside and side of the neck of the male was more reddish or reddish brown than the female. The present female was red or reddish brown on the neck and shoulder region. This supports the statement of Fan (1931) that red coloration in this species varies between individuals and is not a sexual character. Sprackland (1989) states that both sexes are red along the neck, flanks, and throat and suggests males may be more intensely colored. This specimen did not shed until 21 May 1990, when large patches were observed peeling away. The pieces of skin remained floating in the water for three days, suggesting that the shed skin is not routinely eaten. Ecdysis occurred again on 20 July 1990.

Longevity. This specimen is still alive 8 August 1990; captive longevity of adults thus exceeds one year.

ACKNOWLEDGMENTS

I thank Yang Da-Tong (Kunming Institute of Zoology) for translating the paper by Shen and Li (1982), and Wang Ping (Department of Biology, Lehigh University) for translating the paper by Huang (1983). Comments by Martin J. Rosenberg, Matthew J. Draud and two anonymous reviewers greatly improved the manuscript.

Gekkonid Lizards as Prey of Invertebrates and Predators of Vertebrates

Gekkonid lizards are regarded as being chiefly insectivorous (Loveridge 1947; Kluge 1967; Bustard 1968a). In turn, their primary predators are larger vertebrates such as birds (Bustard 1968b; McKeown 1983) snakes (Pitman 1974), mammals (Whitaker 1973), and larger lizards (Pianka 1986; Auffenberg 1981; Bustard 1968a, b). However, the size range spanned by living geckos (approximately 20-250 mm SVL) is broad enough to encompass deviations from these generalizations at both ends of the scale. Larger geckos can and do eat other vertebrates, particularly other geckos, but also a variety of lizards, frogs, and even birds and mammals. Small geckos, on the other hand, are well within the size range of prey items of larger species of arthropod predators, such as arachnids.

Geckos as Prey of Invertebrates

Reports of attacks by arthropods on small vertebrates are numerous (McCormick and Polis 1982). Arachnids are the most frequently cited predators in these instances. Scorpions have been observed to capture mice (Kock 1969; Piasecki and Newlands 1985), leptotyphlopid snakes (Anderson 1956; Polis 1979) and a wide range of lizards (e.g. Banta 1957; Hadley & Williams 1968) (although some of the attacks on reptiles occurred in the unnatural conditions of a pit-trap). Spiders, too, are known to capture vertebrates, including rodents, birds, frogs, snakes, and lizards, both in webs (Groves and Groves 1978; Neill 1948; Anonymous 1985; Konig 1987; Cokendolpher 1978) and, in the case of terrestrial species, on the ground or in burrows (Caras 1974; Anonymous 1985).

A second group of predators on vertebrates are centipedes, especially members of the genus *Scolopendra* which have been implicated in attacks on toads (Carpenter and Gillingham 1984), rodents (Shugg 1961; Clark 1979), birds (Anonymous 1985), lizards (Lawrence 1953; Butler 1970) and snakes (Easterla 1975).

Although certain cases of insects as predators on lizards are primarily based on laboratory and pit-trap encounters (e.g. Banta 1962), at least some insects, such as belostomatids (giant water bugs) and mantids are quite capable of taking many smaller vertebrate taxa as prey (see McCormick and Polis 1982). Aquatic insects and insect larvae frequently attack and consume fish, and amphibian larvae and eggs, (Heyer et al. 1975; Caldwell et al. 1981; Young 1967; Neill 1968; Wager 1965; Kluge 1981; Villa et al. 1983).

Geckos as a group are particularly vulnerable to attack by arachnids and centipedes, first because of their generally small size (Russell and Bauer 1986) and second because they are chiefly nocturnal, as are these putative predators. The array of predators identified in attacks on geckos includes scorpions, solfugids, spiders, centipedes, mantids, and ants (see Table 1). The prey geckos include representatives of the subfamilies Gekkoninae, Diplodactylinae and Eublepharinae and range from very small forms (e.g. *Tropiocolotes*) to moderately large species (e.g. *Diplodactylus* and *Hemidactylus*). Species from all continents inhabited by geckos are represented. The majority of the geckos are terrestrial or rupicolous, although a number of arboreal species have also been attacked by each type of arthropod predator.

Although most instances of arthropod attacks on geckos are based on fortuitous observations of single events, certain spiders, scorpions, and insects derive a substantial portion of their energy input from vertebrates and in turn account for a sizeable percentage of small vertebrate mortality (McCormick and Polis 1982). Spiders have been implicated as major predators on *Garthia [=Homonota] dorbignyi* (Donoso-Barros 1966), *Phyllodactylus porphyreus* (pers. obs.), and *Diplodactylus* spp. (Minton 1983; Kluge and Schuett 1986). In the case of *Diplodactylus*, the evolution of a unique caudal defensive mechanism has been tentatively linked to predation attempts by lycosid spiders (Kluge and Schuett 1986). Unfortunately, the mechanism of ingestion of most arthropods, and especially arachnids, precludes facile analysis of gut contents, and quantitative estimates of the ubiquity and significance of geckos as prey of these arthropod predators is not possible. Nonetheless, it would appear that many geckos, for which no observed acts of predation by arthropods have been reported, may be especially susceptible to attack. In particular, small leaf-litter dwelling species, such as most of the sphaerodactyline geckos of the Neotropics, are within the size range of insects (hatchlings as small as 5 mm SVL) and are broadly ecologically comparable to syntopic insects, feeding largely on tiny collembolans (Gasc et al. 1983), and in turn providing food for predatory arthropods.

Geckos as Predators of Vertebrates

Many large lizards, such as varanids, are primarily carnivorous, feeding to a large extent on other vertebrates (Cowles 1930; King and Green 1979; Auffenberg 1981; Pianka 1982, 1986). Among gekkotons, only the pygopodid *Lialis* specializes almost exclusively on vertebrate prey, chiefly skinks (Patchell and

Shine 1986). Geckos, on the other hand, have been regarded as "classic" insectivores. In reality, geckos as a group are rather catholic in their diets within the limitations of their body size. A number of taxa, especially insular forms, have become frugivorous or nectivorous (although not exclusively). These include *Rhacodactylus* in New Caledonia (Bavay 1989; Bauer 1985), *Gehyra* in Fiji (Gibbons & Clunie 1984), *Hoplodactylus* in New Zealand (Whitakerd 1968, 1982, 1987a, 1987b) and *Phelsuma* in the Mascarene Islands (Vinson 1949; Vinson & Vinson 1969) and the Seychelles (Gardner 1984). Another much more geographically and phylogenetically diverse group of geckos has adopted another "unorthodox" set of prey items, other vertebrates.

A minimum of 37 species of geckos (or about 3-4% of known species) have been implicated in vertebrate predation (see Table 2). Other geckos, including conspecifics (mostly juveniles and eggs) are the most frequent victims of predation (see Rösler 1984, 1988; Mitchell 1986). Geckos involved in these interactions span a wide range of sizes and again represent three subfamilial units. Predation on other lizards, specifically lacertids and skinks, has been reported in a variety of terrestrial geckos (Minton 1966; Pianka and Huey 1978; Bauer 1990) and in several arboreal forms (Salvador 1978, 1981; Rieppel 1981). Gecko predation on birds and mammals is reasonably rare and most instances represent feeding events under captive situations. Nonetheless there are a number of reports of gekkonids preying upon bats (Kluge 1967), small birds (Roux 1913) and rodents (Sumithran 1982) under natural conditions. A particularly interesting case is that of *Cyrtodactylus cavernicolus*, a Bornean cave-dwelling gecko that feeds upon baby swiftlets that fall from nests on the cave walls (Harrison 1961).

The gecko taxa that feed on vertebrates include many of the largest gecko species (Russell and Bauer 1986) which, as suggested by Loveridge (1947) probably opportunistically feed on any prey that can be subdued and ingested. *Gekko gecko* is particularly aggressive and has been said to be predatory on birds, mammals, lizards and even snakes (Smith 1935; Boulenger 1912), it has also been credited with fighting off attacking snakes, including *Elaphe* (Curran 1932) and *Chrysopelea* (Flower 1899).

Although the two genera *Hemidactylus* and *Nephrurus* are particularly well represented in the survey of predatory geckos, it is unlikely that this is of particular significance. The ecology of the latter genus has been unusually well studied (Pianka & Pianka 1976) while the former is extremely speciose and contains many taxa which are commensal with man and are thus particularly conspicuous to human observers.

DISCUSSION

Contrary to expectations, size alone does not appear to be the major factor in the occurrence of gecko species in either of the two groupings delineated above. Only the largest geckos are immune from arthropod attack while even the smallest may be cannibalistic. Likewise no phylogenetic grouping appears to have any predictive relations to the trophic interactions of geckos. Rather, terrestrial and rupicolous geckos, as well as commensal species appear to be more likely to succumb to invertebrate predators and to take vertebrate prey themselves. However, the trophic relations of so few geckos have been examined that it is likely that many or most gekko species are occasionally taken by invertebrate predators or feed on vertebrates.

TECHNIQUES

A REFINEMENT OF THE STOMACH-FLUSHING TECHNIQUE FOR SMALL SCINCID LIZARDS

Stomach flushing is a widely used technique for studies of the diets of animals when destructive sampling is undesirable and has been adapted for use on a variety of taxa (Randall and Davison 1981; Wilson 1984; Moll 1989; Lewis 1989). Since the description of a technique for stomach flushing turtles (Legler 1977), the procedure has been used on a variety of lizard taxa (e.g. Legler and Sullivan 1979; James et al. 1984; Shine 1986; Henle 1989a, 1989b). During a mark-recapture study of scincid lizards of the genus *Ctenotus* in central Australia, I desired to collect stomach contents without killing the lizards. Seven species ranging in adult body-mass from 3 to 15 g (45 to 100 mm snout-vent length) were stomach flushed. Early attempts at stomach flushing resulted in a number of deaths, principally from damaging the stomach wall, forcing water through the pyloric sphincter into the intestines or shock characterized by respiratory failure. The following note describes refinements made to the equipment and a method for dealing with shock and respiratory failure after stomach flushing.

The lizard's mouth was forced open by applying gentle pressure on the posterior end of the quadrate bone of the lower jaw. The mouth was held open during stomach flushing with a plastic cuff similar to that described by Legler and Sullivan (1979), which was held in place with a thin strip of masking tape wrapped around the snout. Plastic cuffs were cut from cross-sections of syringe tubes and ranged in diameter from 7 to 11 mm depending on the size of the lizard. A thin tube lubricated with K-Y Jelly®, attached to an automatic pipetting device (Legler and Sullivan 1979), was fed down the esophagus to a pre-determined depth. This depth was obtained by measuring the tube against the outside of the lizard to a point just posterior to the forelimbs which corresponded to the midpoint of the stomach. Measuring the depth of insertion of the esophageal tube helped to prevent damage to the posterior region of the stomach and reduced the incidence of water flushing into the intestines.

The lizard was held head-down over a

container and water was gently pumped into the stomach. When the stomach was full of water, pressure in a posterior-to-anterior direction was applied to the stomach to loosen the food bolus. The stomach was repeatedly filled with water and palped. Stomach contents were usually regurgitated on the third or fourth stomach-full of water. Large food boluses often lodged in the throat but were easily removed through the mouth cuff with forceps.

Esophageal tubes were adapted from thin, pliable venous cannulae used in veterinary science and ranged in diameter from 0.8 to 1.7 mm. To prevent water being forced through the pyloric sphincter, the end of the tube was closed with a bead of silicone rubber and two sub-terminal, lateral holes were made. Water emerged sideways from the tube and the smooth, rounded silicone bead in the end reduced damage to the stomach wall. During the initial attempts at stomach flushing *Ctenotus* I found that an open-ended tube frequently punctured the stomach wall. A closed tube with a silicone bead over the end reduced the incidence of stomach perforation.

After all prey items had been removed, the plastic ring was removed and the lizard was placed in a bucket to recover. Approximately half of the stomach-flushed lizards were alert immediately, or recovered within a minute. However, some lizards were virtually unconscious after flushing and sometimes ceased breathing. Left undisturbed in the bucket, some of these individuals resumed breathing without assistance; after 30 to 60 s they would take a large 'gulp' of air and breathe erratically over the next minute. After 1 or 2 min, regular breathing was re-established and the lizard was alert. A small percentage of these deeply shocked individuals would not commence breathing and would die unless aided. In such cases, brief immersion of the lizard in ice-cold water proved successful. A *Ctenotus* typically reacted to this treatment by gasping, followed by irregular breathing as described above. Ventilation of the lungs using a thin tube on a 1 ml syringe was also attempted but was not as simple nor effective as thermal-shock treatment.

ACKNOWLEDGMENTS

I thank Pat Whitaker for supplying me with a range of cannulae for use as esophageal tubes, and Klaus Henle and Rick Shine for discussing their methods of stomach flushing lizards with me. The Commonwealth Scientific and Industrial Research Organization (CSIRO), Central Australian Laboratory provided logistic support for the study.

A METHOD FOR TRACKING TORTOISES USING FLUORESCENT POWDER

Although there are many methods available for determining movement patterns of vertebrates, those most commonly used for terrestrial turtles include: spool and line (e.g. Scott and Dobie 1980), direct observation, mark-recapture (e.g. McRae et al. 1981), and radiotelemetry (e.g. McRae et al. 1981). All these methods have proven useful, but each has disadvantages. The spool and line method utilizes a length of line which is delivered from a spool attached to the carapace. This method is limited to the amount of thread that will fit on one spool and is subject to mechanical failure. Direct observation is labor intensive and human presence may influence behavior of the subject. Radiotelemetry is perhaps the most widely employed method for tracking turtles. This technique is both convenient and relatively long term, once the radio has been attached to the animal. However, it is expensive and lacks precision when determining movement patterns, especially for animals that have small home ranges.

The use of fluorescent powder in animal marking and tracking has gained much attention in recent years. Methods have been developed for marking fish (Jackson 1959) and salamanders (Ireland 1973). Tracking short-term movement patterns in small mammals was reported by Lemen and Freeman (1985). The use of fluorescent powder for tracking island night lizards, *Xantusia* (=*Klauberina*) *riversiana*, recently was reported by Fellers and Drost (1989).

While studying habitat utilization and activity patterns of the gopher tortoise (*Gopherus polyphemus*) at the Black Creek Seed Orchard, DeSoto National Forest, Mississippi, we developed a technique for following movement patterns of adult gopher tortoises using fluorescent powder. With this method we were able to determine the exact route followed by individual tortoises over several days.

The powder is not applied directly to the animal. Instead, a pouch is fashioned from fine nylon mesh; we used panty hose. The pouch should be large enough to contain ca. 5 cc of fluorescent powder. Once the pouch is filled with powder, it is tied closed with small diameter cottor twine. The cotton twine then is attached to the caudal edge of the carapace via a hole drilled through one of the marginal scutes It is important that the pouch be allowed to

drag on the ground as the tortoise moves. Depending on the size of the tortoise, the cotton twine is tied so that there is ca. 4 - 8 cm distance from the powder-filled pouch to the carapace.

We attached fluorescent powder pouches to eight adult tortoises. Tortoises were released at their burrows and their subsequent movement patterns were documented from 3 to 9 September 1989. The dragging pouch left a trail of powder which fluoresced brightly under UV light. A single day's activity was mapped by following the trail at night with a portable UV light source ("Woods Light," available from Henry Schein Inc., 5 Harbor Park Drive, Port Washington, NY 11050, USA (800) 872-4346). Flagging was used to mark the trail more permanently and to avoid confusing one day of activity from the next.

One tortoise either lost its pouch in its burrow or never reemerged during the six-day study period. No trail was observed leading from the burrow after attachment of the pouch. The other seven tortoises produced daily trails after application. Two tortoises produced visible trails for two days. Their subsequent trails were not visible by the third day. The other five tortoises produced daily trails that were easily detectable at the end of the observation period. The maximum distance travelled from a burrow was 22 m and the minimum was 8.2 m (straight line). Direction of movement often could be determined by noting the corresponding tracks left by the tortoise.

This method of documenting activity patterns in gopher tortoises proved to be reliable and accurate for two days or more after application. Although we did not test the pouch in rain, trails left by mammals in whose fur the powder had been applied were almost completely washed away by rain. However, light dew did not seem to affect the trackability of these trails (pers. obs.).

Manufacturer claims indicate that fluorescent powder is nontoxic (manufacturer, pers. comm.); furthermore, our technique does not require that the animal directly contact the powder. More information on toxicity can be acquired from the manufacturer. The trail produced by the powder is also inconspicuous in daylight and should not draw undue attention to the tortoise. The trail is easily visible at night, however, with a UV light source and tends to be more discernible with wear on the pouch as more powder sifts through tears in the nylon mesh.

The pouch is constructed easily and materials are inexpensive. The powder is sold in 1-pint containers which could yield 80 applications per container. The price at the time of the trial was $10.00 per container. The cost for all other materials should not exceed $5.00 per 80 applications. This results in a potential cost of $0.19 per application. The color used in this trial was radiant fluorescent pigment type JST-300, chartreuse 320 (JS-CH3020). However, other colors are available from the manufacturer (Radiant Color, 2800 Radiant Avenue, Richmond, CA 94804, USA, (415) 233-9119).

This technique has several disadvantages. It is necessary to capture the tortoise in order to apply the pouch, and the trails produced by some individuals were visible for only two days. Also, powder deposition and trail visibility depend on weather conditions. The drier the conditions, the better the results will be. Given the gopher tortoise's preferred habitat, this generally is not a problem. It is possible that a pouch might become tangled in vegetation. Though this may have occurred in one case in a burrow, this possibility could be reduced by using the shortest possible line from pouch to carapace.

This method of monitoring movement appears to be particularly suitable for home range studies. Other uses might be determination of nesting sites, burrow use, and dispersal patterns. This method could be used on several tortoises in the same area by using different colors, as has been shown using mice (pers. obs.).

ACKNOWLEDGMENTS

Funding for the Black Creek Seed Orchard Gopher Tortoise Project, DeSoto National Forest, MS, was provided by the U. S. Forest Service, USFS contract 53-44-7U-8-4372 and by the Alabama Agriculture Experiment Station (AAES). This is AAES Journal Series 15-902596P. We gratefully appreciate the donation of fluorescent powder by Molly Bartels and Lee Stribling of Auburn University.

LIFE HISTORY NOTES

See Herp. Review 21(1) *for author's instructions.*

ANURA

PSEUDACRIS FERIARUM (Upland Chorus Frog). **Predation.** Predation of adult anurans by invertebrates is not well documented (Hinshaw and Sullivan 1990. J. Herpetol. 24:196-197). Fewer reports exist on predation by spiders. Goin (1943. Proc. Florida Acad. Sci. 6:143-153) noted that an adult *Acris gryllus* was caught and eaten by a large water spider (*Dolomedes*). On 17 March 1980 I found an adult 22 mm SVL male *P. feriarum* on the edge of a shallow, muddy rain pool 1 mi W Laurel, Henrico Co., Virginia. It was being eaten by a 14 mm (body length) fishing spider, *Dolomedes triton* (formerly *D. sexpunctatus*). The frog was dead and had apparently been envenomated by the spider. Examination of the frog revealed that there was one puncture wound 1.0 mm to the left of the middorsal line, 6.3 mm anterior to the cloaca. The puncture was surrounded by an area of dark pigment.

A large chorus was present on this date and most of the calling males were in the water with about one third of the head and body exposed above the surface. These conditions may have enhanced the probability of capture of this large prey by the smaller *Dolomedes*. I saw no other spider predation on the other anurans

calling at this location (*Bufo americanus*, *Pseudacris crucifer*, *Rana clamitans*, *R. palustris*), although on 8 April 1980 I found an adult *P. crucifer* that had been partially eaten by a crayfish.

Dolomedes triton is well known for its capture and consumption of small vertebrates, including fish (*Gambusia*) and tadpoles (Zahl 1971. Nat. Geogr. 140:190-219). It is a common coinhabitant of anurans in small bodies of water in Virginia. This is the first report of predation by this species on adult *P. feriarum*.

I thank Richard L. Hoffman for assisting with spider identification.

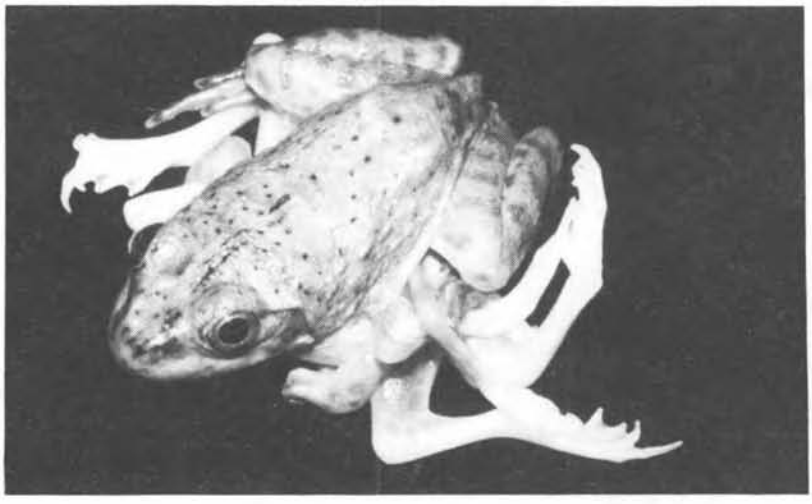
RANA CATESBEIANA (Bullfrog). **Polymely.** The presence of supernumerary limbs (polymely) in anurans is not uncommon (Van Valen 1974. J. Herpetol. 8:109-121). Polymely of hind limbs is variable and is more common than that of forelimbs (Hamilton 1950. Nature 166:611-612). A six-legged frog with a double pair of hind legs accompanied by a doubling of the pelvic girdle was described (Pearson 1960. Copeia 1960(1):50-51). Perhaps the most extreme case reported to date is that of a twelve-legged bullfrog where the eight additional limbs were "growing from the right side of the upper trunk region" (Anon. 1962. Bull. Phil. Herp. Soc. 10(1):24). We report a young male *Rana catesbeiana* that was captured alive in June 1987 in a field pond in Ransome, Illinois (by the R. Stilwill family). This bullfrog had fourteen legs: two normal forelimbs, two normal hind limbs, and ten additional (apparent) hind limbs inserted ventrolaterally behind the forelimbs (Fig. 1A, B). The supernumerary hind limbs were neither functional nor complete in their anatomy. However, the frog did not appear inconvenienced by the extra limbs and was in apparently healthy condition. X-rays of the animal were taken at the Small Animal Clinic, Department of Veterinary Medicine, University of Illinois. Shortly after this (apparently stressful) exercise, the frog died. The animal was eviscerated, cleared using a KOH solution, stained with alizarin red dye, and preserved in glycerin.



The extra legs are embedded in the abdominal wall of the frog and articulate with neither the pectoral nor pelvic girdles. Four limbs arise from right ventrolateral abdominal tissue and are directly inserted into this musculature via three bones (which have the appearance of vestigial and incomplete ossa coxae). Supernumerary limbs on the right side of the frog are not as complete as those on the left side. Of the four right-side limbs, only one has the complete set of bones which form a hind limb. Two other limbs lack phalanges and metatarsals, and the fourth limb has only a femur connected to one of the vestigial pelvis bones.

On the left side of the frog, six additional limbs are present. Many bones converge at the point of insertion of these limbs into the abdominal wall. There is a single bone on the left side (resembling a vestigial os coxa) from which six complete hind extremities arise. In addition, there is a bone resembling no particular structure which also extends out of the body wall from the same origin. Each femur originates from an articulation with an incomplete bone resembling the os coxa. There is no connection to the axial skeletal column via sternal, costal, or sacral articulation. The most distal parts of many medial digits on the left side tend to lack the last phalanx.

The polymelous condition of this specimen differs from other more commonly-occurring anomalies because of the high number of supernumerary legs and because of the ventrolateral insertion of the additional hind limbs. It is known that side-plate mesoderm is competent to induce supernumerary limbs in frogs (Needham 1942. Biochemistry and Morphogenesis. Cambridge Univ. Press, London. pp. 305-308). Induction of polymelous conditions in wild-caught specimens is often attributed to stimulation by injury (Colton 1922. Anat. Rec. 24:247-253) or exposure to chemical contaminants found in the environment (Anon. op. cit.) leading to interference with normal developmental pathways. In this instance, it appears likely that chemical treatment of agriculturally important croplands had some effect in the anomalous development of this bullfrog.

RANA CATESBEIANA, RANA PALUSTRIS (Bullfrog, Pickerel Frog). **Predation.** *Rana catesbeiana* and *R. palustris* were observed being taken by a pair of Bald Eagles (*Haliaeetus leucocephalus*) nesting on Swan Island, Perkins Township, Maine, during the summer of 1988. The eagles were observed feeding upon frogs on six occasions during June and July in a pond located 100 m from their nest site along

the Kennebec River. Observations were made with 10 X 50 binoculars from a vehicle at a distance of 300 m from the pond. The eagles captured frogs by hopping after them along the shore of the pond and grasping them with their talons. They then flew to the nest. I observed no evidence of feeding the frogs to the eaglet that was in the nest.
